FOSSIL INSECTS

The Fossil Insects of North America, with Notes on some European Species. By Samuel H Scudder 2 Vols 4to, Illustrated. (New York Macmillan and Co. 1800)

"HE name of Mr S H Scudder is familiar to students of every branch of zoology through his invaluable "Nomenclator Zoologicus" Though that work alone would be sufficient to earn the gratitude of zoologists, yet the author's claims to especial distinction really rest on the results of his investigations into the structure and distribution of fossil insects, and more particularly those of North America.

The magnificent work before us, containing considerably more than a thousand pages of letterpress, and illustrated by no less than sixty-two beautifully-executed plates, as well as by numerous figures in the text, contains, in a collective form, practically the whole of the author's contributions to the history of North American fossil insects, together with much important information relating to those of Europe In reality, however, it treats of more than is revealed by its title, since the author includes under the head of insects not only the animals usually thus designated (which he distinguishes as Hexapods), but likewise the Myriopods and Arachnids Since the issue of the work is limited to 100 copies (each separately numbered), it is probable that it will soon acquire an adventitious value above that which it possesses from its intrinsic ments. Apart from the author's admirable account of fossil insects (in the larger sense of the term) contributed to Prof. von Zittel's "Palæontologie," the work is the only one giving an exhaustive history of the subject, and is therefore invaluable to all interested in this branch of study. And the excellent manner in which the volumes are turned out demands a meed of praise alike to author, artists, and printers. Indeed, the only serious fault in the book is that in the first volume no explanation of the plates is given otherwise than in the satisfactory condition, Mr. Scudder, at the commencetext, at the close of the articles they severally illustrate.

The first of the two volumes treats exclusively of the pre-Tertiary insects, and consists of a reprint of upwards of twenty articles and essays published in various serials. dating from December 1866 to September 1890 The second volume, which is a replica of the one recently issued by the U.S. Geological Survey of the Territories, formerly under the charge of the late Dr. F. W Hayden. contains practically the whole of what has been written concerning the Tertiary fossil insects of North America. in which field the author, with one small exception, is the sole worker

In the first volume, as we are informed in the introduction, the whole series of essays shows the manner in which the author's views have been gradually modified in certain respects with increasing knowledge, and we think he has exercised a very wise discretion in allowing the articles to stand as they were written, and thus permitting the gradual evolution of his later views to be traced

The earliest known true insect is Palaoblattina of the lower part of the Upper Silurian of France, regarded by its describer as a cockroach, although considered by our author as probably one of the Neuropteroid Palæodictyoptera (p 286); but with this exception the insects from the Upper Devonian of the United States claim the earliest position. It is, however, only (as the author tells us elsewhere) when we reach the coal-measures that we find insect-faunas of any considerable extent, such as those of France and Illinois The Permian, if, with the author, we refer the coal of Saarbruck to the Carboniferous, is, however, poor in insects; and the Trias, with the exception of that of parts of Colorado, almost barren. The later Secondary beds of America are likewise very barren of insect-remains, so that we have to turn to Europe to gain any definite knowledge of the fauna of that date In the Tertiaries abundant insect-faunas occur in several river and lake-basins of both hemispheres; two of the most celebrated being the Florissant basin of Colorado, and that of Eningen on the Rhine.

The wings of the Palæozoic insects being those parts of the body which are most commonly preserved in a ment of his studies, devoted particular attention to this subject, and the first volume commences with an inquiry into the relationship of the Neuropterold insects of the North American Carboniferous to the existing Neuroptera, as exemplified by the structure of their wings. It would be out of place here to allude to the variations in the structure of the veins of the wings presented by different groups of insects, and their derivation from a common plan of structure; and we may accordingly proceed to notice the most interesting chapter in the whole volume. This is the essay on Palæodictyoptera, commencing on p 283. Here we have a detailed account of the reasons which induced the author to separate the whole of the Palæozoic insects from the existing orders under the name of Palæodictyoptera-a term first proposed by Goldenberg in lieu of Dohrn's preoccupied Dictyoptera, which had been suggested for an order typified by the Permian Eugereon This order is defined more by the generalized characters of its various members, and the lack of those special characteristics which are the property of existing orders, than by any definite peculiarities of its own One of its most important features is, however, that the two pairs of wings are always closely similar to one another, being equally membranous, and with the six principal veins always developed. With the exception of a few cockroach-like insects found in the American Trias, the Palacodictyoptera not only includes all the insects of the Palæozoic, but is restricted to that period, and is, therefore, extremely convenient to the geologist. The order is divided into various sections, which are severally regarded as the ancestors of the existing orders whose names they bear. Thus, the Palæozoic cockroaches constitute the Orthopteroid Palæodictyoptera while we have a Neuropteroid section represented by Platephemera, Mianua, &c : and an Hemipteroid one by the above-mentioned Eugereon. The presence in wood of Carboniferous age of borings similar to those made by modern Coleoptera, further suggests the existence of a Coleopteroid section of the order The author (p. 320) considers that such Coleopteroids "at first showed no greater distinction between the front and hind wings than existed in other Palmodictyoptera, but afterwards those races were preserved in which the thickening of the membrane of the upper wings the better protected the insects in their burrows for the marriage flight in open air."

The author gives a still fuller account of the reasons for adopting the order Palledottyoptera, in the essay on "Winged Insects from a Palacontological Point of View" (p. 317), from which the preceding extract is taken. Great stress is there laid on the fact that the differentiation of wing-structure characteristic of modern insects did not exist in those of Palacontic cutients; all of them having a common type of neuration barely admitting of division into families. The differences in the organs of the mouth, as exemplified by the biting Prognoslatina (a Palacontic occhorach) and the suctorial Eugeron, are considered merely as physiological adaptations of no morphological value (pp. 246, 285).

The facts and arguments detailed by the author leave, then, no doubt as to the close affinities and undifferentiated characters of all the Paleozolc insects; and also that the group Paleodictyoptera includes the ancestors of a considerable number of the existing orders of insects.

Since, however, all the latter are clearly divergent branches from one or more common stocks, and are in no sense ancestral to one another, the suggestion arises whether it might not be advisable to group all the existing orders together-say, under the name of the Neodictyopterine "series"; and to rank the Palæodictyoptera as a series" of equal value, in which the various members were not sufficiently differentiated from one another to constitute "orders" It is a very significant fact that, while the Palæozoic insects show ancestral forms of those recent orders grouped together by Packard as the Heterometabola, they include no ancestral types of the more specialized orders-Lepidoptera, Hymenoptera, and Diptera-constituting the Metabola We have, therefore. proof that these specialized types are of later date; and it thus appears that palæontological evidence is in favour of Packard's classification 1 Of the existing orders of insects it appears, indeed, that while the Neuroptera, Orthopters, and Coleopters are more or less fully represented in the Trias, it is not till the Lias that we meet with Hemiptera (Rhynchota), although Eugereon may be taken as sufficient evidence that a Triassic member of that order must have existed None of the Metabola are known before the Lias, the Diptera and Hymenoptera dating from that epoch, while the Lepidoptera are unknown till the Middle Jurassic

Though space does not permit of much further reference to the true insects of the pre-Tertiary epochs, we cannot pass over the interesting essay (p 323) on the oldest known insect larva. These larvas, which appear to be very abundant in the Trias of the Connecticut River. are known as Mormolucoides (Palebhemira), and there has been much discussion as to whether they indicate Coleopteroid or Neuropteroid insects Mr Scudder's mode of treating this difficult question is a model of palæontological induction After carefully reviewing all the evidence, he concludes that the fossils come nearer to the larva of the Neuropterous families Perlide, Ephemeride, and Stalide, and that the relationship is nearest to the latter family, which belongs to the true Neuroptera Another exceedingly interesting article (p. 433) refers to the cockroaches of the Fairplay beds. Colorado. Several of the species from these beds belong to the Palæodictyoptera, showing the complete interdependence of two of the veins of the fore-wing characteristic of the Palæozoic types Others, however, are true Orthopteroid cockroaches, and we thus seem to have presented to our view the very period when the Palæodictyoptera were passing into the Orthoptera. From the mingled Palseozoic and Mesozoic facies presented by their insect fauna, the author is disposed to refer the Fairplay beds to the Trias, although, as is so frequently the case, the plantevidence does not accord with that presented by the

Passing to the Palizonic Myriopods, we notice that while all the forms described in the earlier essays are clearly referable to extinct ordinal groups, the progress of discovery has recently shown (p. 393) that side by side with these lost types there existed in the Coal measures of Illinois Centipedes closely allied to existing forms, and

Many ambornies, attaching more importance to the nature of the metamorphosis, transfer the Coleopoura to the higher group (Melounstabela), is which some also include the true Neuroptera, placing the Pseud neuropter with the Orthoptera.

belonging to the same ordinal group (Chilopoda). The essays respectively commencing on pp. 195 and 247 of the first volume give the full history of the specimens on which the author founded the orders Protosyngnatha and Archipolypoda. The former group is represented only by a single specimen from the Carboniferous of Illinois. described as Palaocampa; this curious creature being of small size, and in its short body, with pencils of bristles on the back, presenting a superficial resemblance to the well-known larva of the tiger moth. Of more interest are the Archipolypoda, confined in America to the Carboniferous and Permian, although represented in the "Old Red" of Scotland A restoration in Plate vii. A, of one of the largest of these creatures (Acantherpestes) gives an excellent idea of their extraordinary appearance, the animal being represented as emerging from the water and ascending the stem of a Lepidodendron. The figured species attained a length of about one foot : its amphibious habits being inferred from the presence of lateral apertures presumed to be branchial The Archipolypoda agree with the Diplopoda, or Millepedes (and thereby differ from the Chilopoda), in having two ventral plates, each carrying a pair of limbs, to every dorsal plate, but differ in that each dorsal plate occupies at most only two-thirds, instead of nearly the whole of the circumference of the body. The larger species, like the figured one, were further distinguished by carrying rows of long spines on the dorsal plates The smaller forms originally discovered by Sir I W. Dawson in the Sigillarian stems of Nova Scotia, which were doubtless of purely terrestrial habits, and have been described as Xylobius and Archsulus, appear to indicate a distinct group of this order approximating to the modern Millepedes

As an instance of the danger of drawing inferences in palæontology from negative evidence, we may quote a sentence from p 196 of the first volume, where the author states that "The Diplopoda are universally considered the lower of the two in their organization, and it is therefore not surprising to find that no Chilopoda have been found in rocks older than the Tertiary series, while Myriopods with two pairs of legs corresponding to each dorsal plate range back through the entire series of rocks to the Coal-measures" This inference is, of course, completely traversed by the above-mentioned discovery of Carboniferous Chilopoda; and it may be suggested whether the presumed coalescence of two dorsal segments in the Diplopeds and Archipolypeda is not a character in advance of the Chilopoda.

The only essay devoted to Arachards in the first volume is the one commencing on p. 419, which was originally published for the first time in September 1890. This easy treats of the Palescole order Anthracomatti, and of that division of the Pedipalpi known as the Phrynides; the Scorpions being reserved for a future occasion. The Arachards differ from both the insects and Mynopods in being represented by an existing order (Scorpions) as far back as the Shurian Indeed, the only extinct order of the class is the Anthracomatti, which is confined to the Carboniferous, and is regarded a having some points of connection with the Aleitarhosomists, as represented by the Phalangida ("Harvestimen"), and others with the Pediapalpi, the Teationship

being on the whole nearer to the latter. They are characterized by their somewhat depressed bodies, in which the abdomen is distinct from the cephalothorax, and consists of a single mass composed of from four to nine distinct joints; while the palpi are short, and do not terminate in pincers or claws. With the possible exception of the Scorpions, these appear to have been the most abundant of the Carboniferous Arachnids, and were represented by a number of genera; those described in the essay before us being arranged in two families and six genera. In the Phrynidean section of the Pedipalpi, containing the Spider-Scorpions, Mr Scudder describes a new Carboniferous genus, Graophonus, besides giving further characters of a previously-described species of Ceralinura. whose nearest living ally is Thelythonus, of the tropical regions of Asia, America, and Australia

Passing to the second volume, on the Tertiary insects, of which only a very brief notice can be given, we may touch upon a few points mentioned by the author in the introduction One of the most noteworthy circumstances to which he refers is the extraordinary profusion in which insect remains have been preserved in some of the Tertiary lake-basins of North America, this being especially the case with the Florissant basin of Colorado, belonging to the Oligocene epoch Not less remarkable is the fact that in "liardly a single instance has the same species been found at two distinct localities", and this not only when the localities are separated by hundreds of miles, but even when they are comparatively near. The author considers that this peculiarity may be explained by the absence of exact synchronism between any of the insectiferous beds, and he is thus led to infer that insects will probably afford very valuable aid in determining geological horizons, the modification of species having progressed much more rapidly than is the case with plants

Another point to which attention is directed relates to the extraordinary number of forms known only by a single specimen, the author stating that, it beds whence thousands of insects have been obtained, every third or fourth specimen will prove to be a new form. The interest of these investigations is enhanced by the discovery that a considerable proportion of the Fertiary invests must be referred to extinct genera, the author considering that a large number of the species he has placed in existing genera will eventually have to be removed to new ones. We trust, however, that Mr Scudder will not burden the science with more new terms than are absolutely essential; more especially since, if he favours us with a new edition of his "Nomenclator," he will have the additional labour of recording them as second time.

Following the introduction there is a chapter desorded to the American localities where fossil Tertairy insects are most abundantly found. In addition to the Florissant basin of Colordo, there are deposits of approximately the same age on the White River in Colorado and Utah, as well as on the Green River in Myoming. Less productive spots include a town in Myoming, rejoicing in the appropriate name of "Fossil," as well as various places in British Columbia, Ontario, and Pennsylvania. There are also a certain aumber of insects—mostly Colorpera—from Pleistocene or recent bone-caves and other superficial deposits.

By far the greater bulk of the enormus collection with which the author has had to deal was obtained from the Florisant basin; and it is to these alone that from the Florisant basin; and it is to these alone that the present volume (large as it, however, so vast that in the present volume (large as it, however, so vast that in possible to deal only with the Arachnids, Myriopods, and the Neuropiers, Hemiptera, and Orthoptera among the true insects. Some introductory remarks are, however, great as to the relative proportions in which the Lepidoptera, Hymenoptera, Diptera, and Coleoptera, are represented in these beds.

The total number of specimens of insects obtained from Florissant during the labours of a single summer is estimated to be more than double that obtained during thirty years at the celebrated European locality, (Fningen A remarkable difference occurs between the relative number of species of the different orders of insects found at the two places. Thus, while at (Lningen the Diptera are less than 7 and the Hymenoptera less than 14 per cent of the whole; at Florissant they reach respectively 30 and 40 per cent On the other hand, while the (Eningen Coleoptera form nearly half of the whole number, at Florissant they fall to 13 per cent The great percentage of rlymenoptera is due to the prodigious number of ants; in which respect, as also in the small proportion of beetles, the fauna agrees better with that of Radaboj, in Croatia, to which it likewise approximates more closely in age. It would take too much space to enter into the details of the proportions in which the various families of the different orders are represented in these beds, but it appears that, with the exception of the Lepidoptera, nearly every prevalent family may be demonstrated to have been in existence at that epoch Among the beetles, about three-fifths belong to the normal series, and the remaining two-fifths to the weevils; water-beetles being unexpectedly scarce | Lepidoptera are rare, only eight species of butterflies, all referable to different and extinct genera, and about the same number of moths being at present known it is of especial interest to note that, while seven of the eight butterfies belong to the Nymphalida, no less than two of these are referable to the sub-family Libytheina, the members of which, although found in every quarter of the globe, are fewer in number than many other groups, consisting only of ten species, referable to the single genus Libythea It is, therefore, a legitimate inference that the Libythema have been on the wane since the Oligocene or some later Tertiary epoch Some writers, it may be mentioned, regard Libythen as the representative of a family rather than a sub-family

In taking leave of the author, we congratulate hum on the patience and perseverance which have carried him thus far through a tax's of unusual magnitude and difficulty, and hope ere long to have the pleasure of welcoming its completion. With the widely-extitered literature of patienticles yet even increasing, the importance and value of monographs like the present, where the whole subject is collectively treated by a master-hand, cannot be too highly estimated.

² (Eningen is situated on the right bank of the Rhine, between Shaffhaus and to the Bades, and not, as the au hor states on p st, Bayers.

NO. 1123, VOL. 44

STATISTICS OF POPULATION AND DISEASE.

Studies in Statistics. By George Blundell Longstaff.

"S TUDIES" as a title appropriate to these somewhat detached investigations concerning at least three different classes of subject. The first few chapters, relating to vital statistics, are described by the author as "of an introductory and elementary character"; though the discussion which is contained in one of them, on the fluctuation of death-does not appear to us so very radimentary of death, does not appear to us so very radimentary.

or teating, does not appear to a secretary with the "growth of population" when the bob "missing increase" or fining paration. English and wales alone add 1000 a day of the bob will up the gape caused by death, a fresh regiment at foll was terriging daily marches to the front. "To what quarters are they marching? The answer may over a consideration of intra-migration, as Mr. Longstaff terms the migration between the several divisions of the same kingdom. The incurry brings into vision the relatively slow increase of rural as compared with urban durities," accorning to the United Kingdom.

These and other facts, extracted from records accessible to all, are not absolutely new to the student of Statistics Yet they excite gratuited, almost as much as if they were wholly due to the author, enhanced as they are by the wealth of his inferences and the luxury of his illustrations.

The statistics of the growth of America are less familiar to the English reader By a carefacil By a partial analysis of the American census, Mr. Longstaff estimates that nearly one-third of the whole populsion (almost 35 per cen!) is "foreign"; considering as foreign not only those born of foreign parents (whether in American or elsewhere), but also half of those who, though native-born, have one foreign parents (whether in American or elsewhere), but also half of those who, though native-born, have one foreign parents (whether yellow) and political danger, particularly in the case of the rapidly growing coloured population in In more than sense, says the author, a black cloud may be said to bang over the future of the Republic.

Canada is not equally threatened by the dangers anising from a mused population. Yet, even in Canada, the fact that the persons of French race form about a third part of the population, and increase more rapidly than any other known people, "cannot but be a source of anisety and possible trouble in the future." The solidity of our Australian colonies is more perfectly satisfactory.

Surveying the British Empire, the writer colbibits the growth of the colonies relatively to the mother country during the last half-century. Whereas the ratio between the populations of the colonies and the United Kingdom was 7, 100 in 1841, it had become 21 100 in 1881. Entertaining the dead of an Imperial Federation, our statistical thus estimates the balance of power in the imagined Federal Parliament. If every 100,000 of white population are entitled to one representative, then of per cent of the Imperial Parliament would be Engish; the proportions for Scotland and Ireland would be 3 and 13 per cent. respectively.

But the political interest of these estimates must not detain us from what is perhaps the most severely scientific part of the work before us-namely, the investigation of the causes of disease. This medical portion of the volume may, as the author fears, "prove too technical for many readers"; and, perhaps we should add, critics. The student of such statistics must bring much knowledge in order to carry away much. The need of this requisite may be illustrated by one of Mr. Longstaff's examples Certain of the curves which he traces show a remarkable correspondence between the outbursts of diphtheria and a group of other diseases, amongst which are croup and cynanche maligna. And yet between the two latter diseases and diphtheria the correspondence at some dates is not so close as the suggested theory desiderates Diphtheria in 1850 rose enormously, while the other diseases did not rise simultaneously, or even feil But, as we understand the matter, the theory is saved by the surmise that many cases previously ascribed to croup and cynanche maligna, were put down to diphtheria in 1859 and afterwards, when the stir created by letters in the newspapers had excited the attention of observers to the "new disease" This is one of those explanations of figures which an outsider would probably not even have thought of, and the importance of which he is little qualified to estimate

The "ætiology" of the subject must be left to the expert. The general reader, if he cannot penetrate to the laws of causation, may at least admire the uniformity of results which the author's diagrams exhibit. The nature of some of his observations, and the labour and care which they required, are indicated in the following quotation -

"The object of my investigation was . [principally] to see whether any, and if so what, relations subsist between diseases believed to be distinct. . . I accordingly traced eighty-nine curves representing the death-rates per million in England and Wales from as many 'alleged causes.' . . By a simple application of the law of combinations, it will be found that to compare all these eighty-nine curves two and two together, would involve 3916 operations Of these I have as yet actually made only 1225"

This comparison of curves representing the fluctuation of death-rates for different diseases forms some of the most beautiful pieces of statistics which we have ever We may allude in particular to the comparison of erysipelas, scarlating, rheumatism of the heart, and certain other diseases with each other and the variations in the rainfall (Plate xix.). The death-rates are shown to be parallel to each other, not only for different times, but also, in the case of three of the diseases, for different places in all the eleven registration counties of England and Wales. The splendid diagram which exhibits this manifold comparison (Plate xxi.) affords, as the author points out, a good illustration of the value of large numbers in statistical inquiries.

"The curves for England and Wales exhibit smaller fluctuations than those for sections of the country, and the correspondences between them [between the rise and fall of death-rates for three specified diseases] are in nearly all cases much closer."

Among investigations of which the interest appeals to the mere statistician as distinguished from the medical expert, we may mention the calculation of the frequency with which coincidences between the deaths of both husband and wife from phthisis "might be expected to occur as a pure matter of chance, on the hypothesis that

NO. 1123, VOL. 44

phthisis is not a communicable disease." By a beautiful application of the calculus of probabilities, the following conclusion is reached:--

"It is plain, therefore, that, to show any substantial argument for the existence of infection, it would require a much larger collection of cases than has yet been published."

Another inquiry which the general reader will follow with peculiar interest relates to hydrophobia. The statistics suggest laws very different from popular beliefs The paucity of the observations, however, necessitates caution; which Mr Longstaff does not fail to inculcate It is not his least merit that he instils what may be called the logic of statistics by occasional precept, as well as by repeated examples

OUR BOOK SHELF.

The Best Books . A Contribution towards Systematic Bibliography By William Swan Sonnenschein Second Edition (London: Swan Sonnenschein and Co., 1891.)

THE idea of this "contribution towards systematic bibliography" is excellent, and has been excellently course.

When interest in a subject has been excited, the first question of the student, of course, is, Who are the best and most recent authorities on the matter? The question is by no means always easily answered, for as yet there are few good subject-indexes, and the most valuable of The present them are not within the reach of everyone volume may almost be said, for ordinary practical purhas not attempted anything so ambitious as a philosophic classification of the sciences He has worked out his scheme on what he properly calls "a common-sense plan," grouping books first into large classes, then breaking them up into sections, sub-sections, and paragraphs-"with the result of obtaining all the literature of one subject in one list, and that of outlying subjects close at band." He begins with theology, next takes mythology and folk-lore, then philosophy, society (including many different branches), geography, history, archaeology, and so on, until all important departments of knowledge have been included. No one who has occasion to use the book will have the slightest difficulty in understanding the principle, or in finding the particular subdivision presenting the facts of which he is in search. edition contains the titles of twice as many books as the first edition (50,000 as against 25,000), and, so far as we have been able to examine them, they seem to have been admirably selected Here we have to do only with the scientific part of the work, and, considering how vast is the material from which Mr Sonnenschein had to choose his lists of scientific treatises, he may be con-gratulated on the manner in which his task has been accomplished. For the most part, he refers only to books that are in print, and easily obtainable The very best books he has "asterisked," and in every case he gives the dates of the first and last editions, with the price, size, and publisher's name. Two separate indexes—one, a list of authors, with the titles of their works; the other, a list of subjects-add greatly to the value of the compilation.

The Fairyland Tales of Science. By the Rev. J. G. McPherson. Second Edition. (London: Simpkin, Marshall, and Co. 1801.)

THIS volume consists of a number of papers which appeared originally in various periodicals. does not profess to embody in them the results of independent research. His object is to give to readers who may not have access to recent scientific authorities "an accurate and at the same time interesting account of the remarkable discoveries in science during the last decade."
This object he attains. His style is clear and straightforward, and, without being "sensational," he knows how to present facts and principles in a way that is likely to surfest attention and awaken curlosity. Among the subjects dealt with are the formation of dew, the colour of water, dust and fogs, lightning, sun-spots, after-glows, the enumeration of organisms in air, micro-organisms in water, and characteristics of deep-sea fishes The first edition was issued about two years ago. In the present facts up to date

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Neather can he undastake to return, or to correspond with the worsters of, rejected manuscripts intended for this or any other part of NATURE.

No notice is taken of anonymous communications 1 County Councils and Technical Education,

Your article of April 30 (vol. xlni p 602) is scarcely fair to the London County Coun

When you allege that the Council "have 'grabbed' a fund, sur-marked for educational purposes," you assume the question at issue. The only way in which the fund in question is "ear-marked" for educational purposes is by a clawe in the Act which gives each Council a discretionary power to supply the fund either to those purposes or to other purposes, as they

choose.

London, which, as proved by Mr. Coschen, is exceptionally rated, has come badly off in the general scramble for imperial doles which are devoted to the allevation of rates, and if the representatives of London ratepayers treat this additional folder out of the beer and spirit dulies as a make up for their con-

out of the ever and spire duties as a make up lot their com-paratively small share of other dole, they are doing not only I believe, however, that amongst those who voted against the plan proposed by the Committee of the Council there are many who would not be unwilling to see the money devoted to educa-tion, if any well-considered and reasonable plan were proposed

for this purpose.

But there are several questions which have to be answered

But there are several questions which have to be answered before this can be done properly.

What do the promoters of "technical education" mean by that term. It is not to be the teaching of the elementary that term. It is not to be the teaching of the elementary that the promoters are the properly of the elementary that the properly of the elementary that the properly of the elements of farming. The counties say, "Tolytechnics", the statute say, "Individend the elements of farming," the London County Council Committee say, "Tolytechnics", the statute say, the elements of the bungs the public meant to the business of his but we need to bring the public meant to the business of his but we need to bring the public meant to the business of his but we need to be a made to the elements of the state of the elements of the

De a practice.

Then, again, is it wise for the London Connty Council, which has work enough on its hands in looking after the physical condition of this great City, to take upon itself a task for which it is in no way fitted, and which was not contemplated when it was in no way fitted, and writer was not contemplated when a was elected. It is wast to must de administration by first intrasting elected to the waste of the state of the state

London Conneil exeremes a wise discretion in not committing itself to any scheme for appropriating this fund, the offspring of alegislative fluke, to any special and permanent object.

You speak, as persons in general speak, of the London County

You speak, as persons in general speak, on the London Lounds, council as one amongst other County Council. The name County Council is a mismoner which leads to constant error. The London County Council has institute or nothing in common with the bodies which have taken the place of the old megitarity in most district. It is really the cheff Town Council of the largest city or aggregation of clies in the world, and the rules and reasoning which, under the fill-frawn and dill-righested Local and reasoning which, under the fill-frawn and dill-righested Local control reasoning which, under the fill-frawn and dill-righested Local control reasoning which, under the fill-frawn and dill-righested Local control reasoning which, under the fill-frawn and dill-righested Local control reasoning which, under the fill-frawn and dill-righested Local control reasoning which, under the fill-frawn and dill-righested Local control reasoning which the fill-frawn and dill-righested Local control reasoning which the control reasoning which the control reasoning which the control reasoning which is the control reasoning which th and reasoning which, under the ill-drawn and ill-digested Local

appropriate. Calling London a county is the parent of endless mistakes; and to abuse the London Council because it is no acting in the same way as the Councils of counties seem dispose to set is no less confused than unfair. May 5.

The Alpine Flora.

I HAD not intended to continue the discussion on this subject, but Prof. Henslow's last letter calls for a few remarks. My

argument, summed up, 18 as follows :-

(1) Alpine plants as a class show certain characters, e.g. dwarfing and compact growth
(2) These characters are advantageous to them. or are gor-

related with such as are advantageous. (3) Although dwarfing, &c , may be produced as the direct

(3) Atthough dwaring, &c., may be produced as the direct result of environment (e.g. poor soil), there is normal variability in respect to size, time of maturing, &c. (4) When in cultivation those plants are selected which show a natural tendency to dwaring, &c., it is found that the charge-ter is inherited, and in this way, dwarfed, early-maturing, and

other peculiar races can be produced

(5) On the other hand, when plants have been dwarfed from growing in poor soil, or otherwise as the result of environment acting directly upon them, there appears to be no evidence to

show that the peculiarity is inherited.

(6) Supposing natural selection to be the only factor, it is (b) Supposing matural selection to be an additionally, to produce the complex cheered to far at they are heightary. At least, so

it seems to me.

To illustrate the point, take Mertensia again To illustrate the point, take Merientia again in Colorado, M. ulbrita grows in ravines, &c., by creeks, it could not pos-sibly grow in the same way above timber-line, with its tall stems and abundant foliage. Yet it gams much advantage in the creek bottoms from its height and rank growth; if it were adwarf, it would be almost or allogether smothered. Above species, M lancelata Thus we have two species frequenting different situations in the same district each is fitted for its station, either, removed to the station of the other, could not exist, In Arctic regions, M sibirica has produced a dwarf variety called drummondis, which is, I suppose, a first step towards the establishment of a dwarf Arctic species

Prof Henslow asks why, if natural selection eliminates tall plants on Alpine summits, it does not also do so lower down? I am not at all clear that it does not, in some cases For I am not at an erear that it does not, in some cases. For example, why is it this plants growing on exposed sea-shores have a tendency to he upon the ground or otherwise to evade the violence of the winds? But when a plant is growing among others, it has to compete with them in raising itself into conspicuousness, and any slight disadvantage from exposure to the winds would be more than compensated by the advantage of being able to spread its flowers and foliage in the sunlight and attract invects

The only plant of any size I found above timber-line on the Sangre de Cristo Range was Chicus exoceptalus, a wonderful

Sangre de Cristo Range was Centra state platfar, a wonderful great thatie, which pare throughout flowers, which are watered by humble-been. But this plant in very prickly and conceal to say on a gegante dwarf, in a, though it scena paradornal to say on a gegante dwarf. The typerdul from the far is coloned, on a finded but very creak as very help altitudes in Coloned, on a finded but very creak as very help altitudes in Coloned, on a finded but very creak as very help altitudes. The coloned, on a finded but very creak as very help altitudes. The same time species, anguirifides in not asserted of from arrays. Now I parsy is coming into calli-vation, it would be micretum to see whether it could be modified to a superfider and how far such modification would be micretum or anguirifier. such modification would be inherited There are other matters one might discuss, but I think I have

Inter are other matters one might discuss, our a table 1 are askeredly written enough 1 merely sak, will Prof. Heaslow give a case in which the direct effect of environment Asi produced inherited dwarfing? Will he sho show that natural selection cannot produce a dwarfed variety, or that artificial selection has not?

T. D. A. COCKERELL.

3 Fairfax Road, Bedford Park, Chiwarck, W., April 27.

MR THISELTON-DYFE, in his interesting letter in NATURE (p 581) does not mention one of the striking theracteristics of the Alpine flora—the remarkable brilliancy of the flowers, as compared with those borre by the same or similar species in Engised. A comparison of this kind made by the memory is no doubt not severely scientife, but those tourists in Switzerland who are in the half of observing flowers will probably confirm who are in the half of observing flowers will probably confirm the confirmation of the confirmation rapout, that makes the colours of lowes nowers so origin. The same, or, I should assert from memory, even greater, brilliancy, will be found in Arctic and sub-Arctic Norway by anyone who visits the Throndhjem district and the coast to Hammerfest in Western Norway notoriously is one of the moistest parts of Europe, but, on the other hand, it has, broadly speaking, no night at midsummer It is thus apparently the quantity, and the quality, of the sunlight that causes the peculiarly vivid colours of Swiss flowers, including those of the pastures from 2000 feet upwards. I have never been in Switzerland in spring, and I cannot therefore judge whether the colours of the flora in the lower districts are also more brilliant than ours; but it will be seen below that Swiss observers find that the high Alpine flora

our great national garden at Kew is peculiarly hadju stuated for the growth of Alpines The situation is low and foggy, and mild muggy weather alternates with night frosts. Above all, the smoke pall of London is peculiarly destructive in connection smoke pail of London is peculiarly destructive in connection with the other diavdamanages of the site. Alpine plants, as Mr. Dyer shows, are, in their natural state, at rest under a cloak of snow during the winter. The least warmth, however, statis them into growth, and the marvellously rapid flowering of many kinds in the oose on the melting of a snow-bed, is one of the most curious sights of the Aligs. The Kew climate (and the general English one too, though to a lesser degree) keens the plants in growth in winter. Then fogs, smoke, and damp collect on the young growth. These enumies are peculiarly liable to attach themselves to the numerous sorts with hairy or woolly

leaves. Then follow night frosts, and the young growth perishes. The application of these remarks is, that it does not follow that, because cold frames are necessities in the culture of Alpines at Kew, they should be used elsewhere in England There has at New, Incy should be used exemines in Segant. Incre has been a long discussion recently on this very point in the guidening papers, and the general belief appears to be, that give a fairly day climate cold frames are injurious, because they excite and keep plants in growth when they should be a treat A sheet of glass suspended over a plant in the open air, so as to shoot off our superfluous rain and to keep off some of our fog, snoot our superfluous rain and to keep oft some of our fog, appears to be much better, for premature growth 1. not stimulated. Alpines should so far as practicable be kept as dry as we can in winter, by drainage, light soil, &c. Theu when growth commences, say in March, they should be well watered each day. Commences, say in march, they should be well wastered sent my claims; it is raining), early in the morning. The plentiful mosture thus supplied to some degree takes the place of the melting snow, and it has dred off before the evening frosts sewe upon the leaves. The plants thus can grow freely in the day because they are surrounded with a moist atmosphere, and they because they are surrounded with a moist atmosphere, and they are kept "stocky" (in gardener's phrase) by the cold at sight, just as they are in fact on the Alpv. Thus it he plan recommended by that great authority M II Corrévon, of the Jardin Alpin d'Acclimatation, Geneva In the direc climate of that Alpin d'Acclimatation, Geneva In the there climate of that the cold, M Corrévon replaces the wow blanket of the Alpa by pine bough fastened closely over his Alpines In England this would, I sear, only make the planet voc. It does not follow that, pile bodiga lakernee closely over an Apines — an Laguan une because may plant in finnes at Kee grow long and citagging and lose their natural habit, they do so in England generally in the because may plant in finness at Kee grow long and citagging and lose their natural habit, they do so in England generally in the pose at. The changes in the habit of Alpines for largely due to the control of the control of

se trawent transportés là-hast sont-elles parées de couleur bien plas wres, hen plus pures qu'elles ne sont cher nons "
M. Corréon gues a number of instances in support of tha, which I will not quote here. In conclusion, in Mr. Dyer correct with the capture of a slight filler on the top." I am aware that when you get to considerable elevations the subsoil in forces now that the exception of a slight filler reason for the well-known mortisary on the Great St. Bernard was that bodies could not be built of the subsoil in forces that the subsoil in forces of the subsoil in force mortisary on the Great St. Bernard was that bodies could not be built of the subsoil of the forces of the subsoil of the force of scool force, and force the subsoil of the forces of the subsoil of the force of the force of the force of the force of scool force, and force the subsoil of the force of scool forces and force of the force of the force of scool forces and force of the force of the force of scool forces and force of the force of scool forces of the forces of scool forces of Alps is frozen, it would not apparently be so where trees grow, and it would be interesting to know the line of subterranean frost, and at what depths below the surface it is permanent at

various elevations. I. INNES ROGERS. Chislehurst, April 27

Co-adaptation

I DO not propose to extend the discussion on this subject beyond the present communication, but I cannot refrain from calling attention to the remarkable discrepancy in the position taken by Dr. Romanes in his last letter (April 23, p and that in his former communication (March 26, p 489), in which he says.—"I do not . hold myself responsible for and that in his former communication (March 20, p 489), in which he says. —"I do not. hold myself responsible for enunciating Mr. Herbert Spencer's argument, which the quotation sets forth. I merely reproduced it from him as an argument which appeared to me valid on the side of 'use inheritance.' For not only did Darwin himself invoke the aid of such inheritance, are in regard to this identical case . . . &c " If words have any meaning, this implies that Dr. Romanes agrees with Darwin any meaning, this implies that Dr. Romanes agrees with Darwin in regarding this case as one in which "use inheritance" played a part. Now, after I have endeavoured to show that this supa part Now, after I have endeavoured to show that this sup-posed case of co-adaptation can be explained without the aid of "use inheritance" at all, Dr. Romanes says that there is no difference of opinion on this point between us I can only say that I am very glad to learn this admission on his part, but why did be quote the argument from Herbert Spencer as "vald on the aid of "use inheritance," "If he did not believe it to be a case of true co-adaptation?" My My Dotta.

High and Low Level Meteorological Observatories.

I HAVE read with much interest your article of the 11th inst I MAVE read with much interest your article of the 11th uses on the results obtained by simultaneous observations in the meteorological observatories at the base and at the summit of Ben News . Ben News invest to a height of only 4370 feet above the sea, and yet we find that the comparison of these observations gives results of a knot that could not be obtained from any using gives results of a kind that could not be obtained from any number of stations all on the same level. Might we not hope for still more valuable results from similar observatories placed at the base and the summit of Eina and Tenerifie? Eina is 10,870 feet high, and Tenerifie 12,200. These would be better than any Alpine stations, because of their perfect isolation Belfast, April 25. JOSEPH JOHN MURPHY.

An "International Society"

An institution with the grandiloquent title of "The Inter-national Society of Literature, Science, and Art," which appears now to be largely totuing for subscriptions, publishes in its prospectus a list of the "Honorary Council," among whom appears "Professor Flower." As I am the only person in this

specias." Professor Flower." As I am the only person in this country to whom such a description could be applicable, and as many of my finends have inquired of me whether I have really given my support to the institution, I, wrote to the secretary to inquire by what authority the name appeared, and received the regime by what authority the name appeared, and received the "Sift." Whe special professor of gibts of action wides the receipt of your favour of Saturday. The gentleman to whom you refer is the well-known Professor Ogliby Flower, of New York. I am sorry the coincidence should have caused you any annoyance. In future printings of our recopectual the Chartsian name shall be inserted, Although this letter was dated March 9 last, I find that the prospectus continues to be usued unchanged, otherwise

catalogue and the property of British Museum (Natural History), May 2, 1891.

ON SOME POINTS IN THE EARLY HISTORY OF ASTRONOMY

X/E have next to deal with the astronomical relations of the horizon of any place, in connection with the worship of the sun and stars at the times of rising or setting, when of course they are on or near the horizon, and in order to bring this matter nearer to the ancient monuments, we will study this question for Thebes, where they exist in greatest number and have been most accurately described

The French and Prussian Governments have vied with each other in the honourable rivalry of mapping and each other in the nonourance rivary of imapping and describing the monuments. The French went to Fgypt at the end of the last century, while the Scientific Commission which accompaned the army, a Commission appointed by the Institute of France, published a series of volumes containing plans of all the chief temples in the valley of the Nile, as far as Phile.

In the year 1844, after Champolhon had led the way in deciphering the hieroglyphics, we became almost equally indebted to the Prussian Government, who also sent out a Commission to Egypt, under Lepsius, which equalled the French one in the importance of the results of the exploration, in the care with which the observations were made, and in the perfection with which they were recorded. Hence it is that in attempting to get informarenored. rience it is that in attempting to get informa-tion from ancient temples it is wise to study the region round Thebes, where the information is so abundant and is ready to our hand.

We have then to consider an observer on the Nile at Thebes, and to adjust things properly we must rectify the globe to the latitude of 25° 40', or, in other words, incline the axis of the globe at that angle to the wooden

It will be at once seen that the inclination of the axis to the horizon is very much less than in the case of London Since all the stars which pass between the North Pole and the horizon cannot set, all their apparent movement will take place above the horizon. All the stars between the horizon and the South Pole will never rise Hence, stars within the distance of 25° from the North Pole will never set at Thebes, and those stars within 25° of the South Pole will never be visible there. At any place the latitude and the elevation of the pole are the same. It so happens that all these places with which archæologists have to do in studying the history of early peoples, Chaldea, Egypt, Babylonia, China, Greece, &c, are all in middle latitudes, therefore we have to deal with bodies in the skies which do set and bodies which do not, and the elevation of the pole is neither very great nor very small. In each different latitude the inclination of the equator to the horizon as well as the elevation of the pole will vary, but there will be a strict relationship between the inclination of the equator at each point and the elevation of the pole. Except at the poles themselves the equator will cut the horizon due east and due west. Therefore everything to the north of the equator which rises or sets will cut the horizon between the east or west point and the north point; those bodies which do not set will of course not cut the horizon at all.

The sun and stars near the equator, in such a latitude as that of Thebes, will appear to rise or set at no very considerable angle from the vertical; but when we deal with stars rising or setting near to the north or south

From shorthand notes of a course of lectures to working men deferred.
The point were revised by in a sit desert during the month of January. The point were revised by in a sit desert during the month of January. The point and point in admit point point point and point p

points of the horizon they will seem to skim along the horizon instead of rising directly.

Now it will at once be obvious that there must be a

strict law connecting the position of the sun or a star with its place of rising or setting. Stars at the same distance from the celestial pole or equator will rise or set uniance from the celestial pole or equator will rise or set at the same point of the horizon, and if a star does not change its place in the heavens it will always rise or set in the same place. Here it will be convenient to introduce one or two technical terms. we generally define a star's place by giving, as one ordinate, its distance in degrees from the equator, this distance is called its deck-Further, we generally define points on the horizon by dividing its whole circumference into 360°, so that we can have azimuths of 90° from each pole to the east and west points We also have amplitudes from the east and west points towards each pole. We can say then that a star of a certain declination will rise or set at such an azimuth, or at such an amplitude. will apply to both north and south declinations

The following table gives the amplitudes of rising or setting (north or south) of celestial bodies having declinations from o' to 64° ; bodies with higher declinations than 64° never set at Thebes if they are north, or never rise if they are south, as the latitude (and therefore the elevation of the pole) there is nearly 26°

> Amplitudes at Thebes.

This being premised, we now pass to the yearly path This being premised, we now pass to the yearry pain of the sun, with a view of studying the relation of the various points of the horizon occupied by the sun at different times in the year. In the very early observations that were made in Egypt, Chaldrea, and elsewhere, when the sun was considered to be a god who every morning got into his boat and floated across space, there was no particular reason for considering the ampli-tude at which the boat left, or came to, shore. But a few centuries showed that this rising or setting of the sun in widely varying amplitudes at different parts of the year

depended upon a very definite law. We now, of course, more fortunate than the early Egyptians, know exactly what this law is. We saw in the last lecture that not many years ago Foucault gave us a means of demonmany years ago roucaut gave us a means of demon-strating the fact that the earth rotates on its axis We have also a perfect method of demonstrating that the earth not only rotates on its axis once a day, but that it moves round the sun once a year, an idea which was undreami of by the ancents. As a pendulum shows us the rotation, so the determination of the aberration of light demonstrates for us the revolution of the earth round the sun.

We have, then, the earth endowed with these two movewe have, usen, the earth encowed with these two move-ments—a rotation on its axis in a day, and a revolution round the sun in a year. To see the full bearing of this on our present inquiry, we must for a time return to the globe or model of the earth

To determine the position of any place on the earth's surface we say that it is so many degrees distant from surrace we say that it is so many degrees distant from the equator, and also so many degrees distant from the longitude of Greenwich we have two rectangular co-ordinates, latitude and longitude. When we conceive the earth's equator extended to the heavens, we have a means of determining the positions of stars in the heavens exactly similar to the means we have of determining the position of any place on the earth. We have already defined distance from the equator as north or south declination in the case of a star, as we have north latitude or south latitude in case of a place on the earth. With regard to the other co-ordinate, we can also say it is at a certain distance from our first point of measureis at a certain distance from our first point of measure-ment, whatever that may be, along the celestial equator; speaking of the stars we call this distance right ascension, as speaking of matters earth; we measure from the meridian of Greenwich and call this distance longitude

The movement of the earth round the sun is in a The movement of the earth round the sun is in a plane which is called the plane of the ecliptic, and the axis of rotation of the earth is inclined to that plane at an angle of something like 23½. We can if we choose use the plane of the ecliptic to define the positions of the stars as we use the plane of the earth's equator In that case we talk of distance above the ecliptic as celestial latitude, and along the ecliptic as celestial longitude. The equator, then, cuts the ecliptic at two points one of these is chosen for the start-point of measurement along either the equator or the ecliptic. It is called the first

point of Aries

We have, then, two systems of co-ordinates, by each of which we can define the position of a star in the heavens : equatorial co-ordinates dealing with the earth's equator, ecliptic co-ordinates dealing with the earth's orbit. Knowing that the earth moves round the sun once a year, the year to us moderns is defined with the most absolute accuracy. In fact, we have three years, we have a sidereal year—that is, the time taken by the earth to go through exactly 360° of longitude, we have what is called the tropical year, which indicates the time taken by the earth to go through not quite 360°, to go from the first point of Aries till she meets it again; and since the equinoctial point advances to meet the earth, since the equinocular point advances to meet the earning, we talk about the precession of the equinoces; this year is the sidereal year migus twenty minutes; then there is also another year called the anomalistic year, which depends upon the movement of the point in the armin's orbit where the earth is nearest to the sun; this is running away, so to speak, from the first point of Anes, instead of advancing to meet it, so that in this case we get the sidereal year plus nearly five minutes.

The angle of the inclination of the earth's plane of

The angre or toe incumation of the cartins points or fortain to the plane of its revolution round the sun, which, as I have said, is something like 23%, is called the obliganty of the etilipie. This obliquity is subject to a slight change; food years ago it was over 24.

slight change; 6000 years, ago it was over any In order to give a concrete idea of the most important

points in the yearly path of the sun round the earth, I have here four globes representing the earth, with another nave here four globes representing the earth, with another globe in the middle representing the sun, showing the four practically opposite points of the earth's orbit, in which the north pole of the axis is most inclined to the sun, the north pole of the axis is most inclined away from the sun; and the two opposite and intermediate points where the axis is not inclined to or from the sun, but is at right angles to the line joining the earth in these two positions.

A diagram (Fig. 6) shows what will happen under these conditions. If we take the two points at which the axis, instead of being inclined towards the sun, is inclined at right angles to it, it is perfectly obvious that we shall get a condition of things in which the movement of the earth on its axis will cause the dark side of the earth

Fig 6 -Diagram showing the equality of the sun's centh distance at the two equinoves N, north pole of the carth, N, south pole, Z, remith of Greenwich

and also the light side represented by the side nearest to the sun both being of equal areas, to extend from pole to pole, so that any place on the earth rotating under to pole, so that any place on the earth rotating under those conditions will be brought for half a period of rota-tion into the sunlight, and be carried for half a period of the rotation out of the sunlight; the day, therefore, will be of the same length as the night, and the days and

nights will therefore be equal all over the world
We call that the period of the equinoxes; the nights
are of the same length as the day in both these positions

of the earth with regard to the sun, But in Fig. 7 we have a very different condition. but in Fig. 7 we have a very different condition. The the north pole is inclined at the greatest angle of 23½ towards, and away from, the sun if I take a point very near the north pole, that point will not, in summer, be carried by the earth's rotation out of the light,

Fig 7 —Diagram abowing the variation of the sun's zanith distance from solutioe to solutioe n, north pole of the earth s, south pole, z, zenith of Green such

and a part equally near the south pole will not be able to get into it. These are the conditions at and near two other points called the solstices.

In each of these globes I have placed a wire to represent the overhead direction from Jermyn Street, London, and if I observe the angle between this direction of the zenith to the sun in winter I get a considerable one; but if I take the opposite six-monthly condition and take the same zenith point, I get a very small angle. In other words, under the first condition the sun will be far from the zenith of Jermyn Street, we shall have winter, and in the other condition the sun will be as near as it can be to the zenith of Jermyn Street, we shall have summer These two points represent the two points in the earth's orbit at which the sun has the highest declination north or south. With the greatest north declination the sun will come up high, appear stationary for a day or two, as it does at our summer solutice, and then go down again, at the other point, when it has the greatest southern declination, it will go down to the lowest point, as it does in our winter, stop, and come up agam—that is, the sun will stand still, and the Latin word solutice exactly expresses that idea. We have then two points when the point of the sun at the latin word solutice exactly a considered that the sun at noon, two others when the have equal altitudes of the sun at noon, two others when the actual to the sun at the equinoxes and the greatest and the least at the equinoxes and the greatest and the least at the estimate of the sun at the solution. The change of declination will be supported to the solution of the sun at the equinoxes the sun by the san set most to the north in sentinger and most to the south in winter. At the equinoxes the sun has always of Decl, so it rises and sets due east and west all over the world. But at the solutions that it is a supported to the solution of 235° No 75°, it will the sun at the solution of the sol

At Thebes, representing Egypt, we find that the sun's azimuth at the summer solstice will be 26° N of E. at rising, and it will be 26° N of W at setting

These solstices and their accompanies are among the string things in the natural world. In the winter solstice we have the depth of winter, in the summer solstice we have the depth of summer, while at the equinoves we have but transitional changes; in other words, while the solstice point out for us the conditions of greatest heat and greatest cold, the equinoves point out for us those are very nearly equal, although of course in the one case we are saying good-bye to aummer and in the other to winter. To people who live in tropical or sub-tropical countries a summer solstice is a very much more definite thing than it is to us. In Egypt the summer solstice was paramount, for it herafield the rise of the Nile. Next came the autumnal equinos, for it marked the height of

Did the ancients know anything about these solstices and these equinoses? That is one of the questions which we have to discuss. Dealing with the monumental evidence in Egypt alone, the answer is aboutled your-whelming. The evidence 1 propose to bring before you then been also also also before the propose to bring before you make the propose to bring before you will be a supply that the propose to bring before you have the proposed to be a supply that the proposed with the proposed to be a supply that the proposed with the propo

First a word as to the general plan of a temple such as we find it in Egypt. They may be arranged a rothecturally into two main groups. Edfou is the most perfect example of one of the first group, characterized by having a pylon consisting of two massive structures right and left of the entrance, which are somewhat like the two towers that one sometimes be consistent to west from the order of our English and the state of our English and the state of the entrance when the entrance when the entrance is the entrance when the entrance is the entrance of th

at Thebes is another example (Fig. 8).

From the entrance-pylon the temple goes stretching adopt through various halls of different sizes and details until at last at the extreme end of the temple what is

called the Sanctuary, Naos, or Holy of Holies, is seached. The end of the temple at which the pylons are distated is open, the other is closed. These lofty towers, and indeed the walls, are sometimes covered with the most wonderful drawings and heroglyphic figures and records. Stretching in front of the pylons, extending sometimes very far in front, are rows of sphunes. This principles

Fig. 5 —Plan of the Temple of Ramses 11 in the Memn ma at Thebes (from Leps us), showing the pylon at the open end, and the sanctuary at the closed ons.

ciple is carried to such an extent that in some cases separate isolated gates have been built right in front and exactly in the alignment of the temple. At Karnak there really are two such temples back to back, and the distance which separates the outside entrances of both is greater than the distance from Pall Mall to Piccadilly; the great temple covers about twice the area covered by

St. Peter's at Rome, so that these were temples of a vastness absolutely unapproached in the modern world.

In Denderah we have an example of the second group, in which the massive pylon is omitted. In these the front is entirely changed; instead of the pylon we have now an open front to the temple with columns—the Greek form of temple is approached (Fig 9).

1 shall not have time to get to the astronomical side of

I shall not have tune to get to the astronomical side of the Greek temples in this course of lectures, but I an anxious to take this opportunity to refer to the transition from the Expyrian form of temple to the Greek one. The east front of the Parthenon at Athens very much more resembles the temple of Denderah than it does the early Expyrian temple—that is to say, the eastern front is open; it is not closed by pylone.

In many Egyptian temples, in the progress from one end to the other, one goes through various halls of different styles of architecture and different stages of magnificence But in the Greek temple this is entirely changed, the approach to the temple was outside, the temple representing, so to speak, the core, almost the Holy of Holes, of the Egyptian temple, and any magnificent approach to it.

Fig. 9 +Plan of the Pemple of Denderal (from Lepasus), showing the absence of a pylon

which could be given, was given from the outside. But although they were quite different in their aspects, they were quite similar in their objects. Some Egyptian temples took bundreds of jears to build, the obelisks were all in single blocks like that on the Embankment, and all were brought for hundreds of miles down the Nile A temple meant to the Egyptians a very serious thing indeed.

So much, then, for a general idea of an ancient temple.

Another point is very striking in these temples, notably in the chief one at Karnak.

From one end of the temple to the other we find the ansa marked out by narrow apertures in the various pylons, and many walls with doors crossing the asis. There are 17 or 18 of these immiting apertures, and in the other temple which is back to back to this one we have bloom as exactly the same way limiting the light which blooms in exactly the same way limiting the light which blooms in exactly the same way limiting the light which construction gives one a very definite impression that every part of the temple was built to subserve a special object, via. to limit the sualight which fell on its front into a narrow beam, and to carry it to the other extremity of the

temple—into the strictuary—which extremity was always blocked. There is no case in which the beam of light can pass absolutely through the temple.

The idea is strengthened by considering the construction of the astronomical telescope. Although the Egyptams knew nothing about telescopes, it would seem that they specially about telescopes, it would seem that they special arrangement in the modern telescope—they wanted to keep the light pure, and to load it into their sancuary, as we lead it to the eyeptec. To keep the light that masses into the evenence of a modern telescope pure, we

F17 to -The axis of the Temple of Karnak, looking south east, from outes the north west pylon (from a photograph by the author).

have between the object-glass and the eyepiece a series of what are called diaphragms; that is a series of rings right along the tube, the inner diameters of the rings being greatest close to the object-glass, and smallest close to the eyepiece, these diaphragms must so be made, that all the light from the object-glass shall fall upon the made.

upon the eyepiece, without loss, or reflection by the tube.
These apertures in the pylons and separating walls of
Egyptian temples exactly represent the diaphragms in
the modern telescope.
J NORMAN LOCKYER.

(To be continued.)

HERTZ'S EXPERIMENTS

I N the last article, a general method of measuring the velocity at which a disturbance is propagated was described. It depended on being able to produce a regular succession of disturbances at equal intervals of These were made to measure their own velocity by reflecting them at an obstacle. Then, by the inter-ference of the incident and reflected waves, a succession of loops and nodes are produced at intervals of half the distance a disturbance is propagated during the time between two disturbances. It is a general method ap-phrable to any sort of disturbance that takes time to get from one place to another. It has been applied over and over again to measure the rate at which various kinds of over again to ineasine the rate at which various kinds of disturbance are propagated in solids, liquids, and gasses. It was applied in a modified form years ago, to measure the length of a wave of light, and, within the last'year, some of the most beautiful experiments on photography ever described are applications of this principle by Herr Wiener and M. Lippmann.

There are three things essential to this experiment : (1) some method of originating waves, (2) some method of reflecting them, (3) some method of telling where there are loops and where there are nodes. We will take them in this order—

(1) How can we expect to originate electric waves? If, when a body is electrified positively, the electric force due to it exists simultaneously everywhere, of course we cannot expect to produce anything like a wave of electric force travelling out from the body, but if, when a body is suddenly electrified, the electric force takes time to reach a place. we must suppose that it is propagated in some way as a wave of electric force from the body to the distant place This, of course, assumes that there is a medium which is in some peculiar state when electric force exists in it. and that it is this peculiar state of the medium, which we call electric force, existing in it, that is propagated from one place to another lt must be carefully borne in mind what sort of a thing this is that we call the electric force at any place. It is not a good name—electric intensity
would be a better one, but electric force has come so much into use, it is hardly to be expected that it can be eradicated now Electric force at any place is mea-sured by the mechanical force that would be exerted at the place if a unit quantity of electricity were there is not a force itself at all; it is only a description of the condition of the medium at the place which makes elec-tricity there tend to move. The air near the earth is in such a condition that everything immer-ed in it tends to move away from the earth with a force of about 1'26 dynes for each cubic centimetre of the body, se. each cubic centimetre tends to move with a force of 1 26 dynes. Now the condition of the air that causes this is never described as volume force existing at the place, though we do describe the corresponding condition of the ether as electric force existing there; and as volume force existing would be a very objectionable description of the condition of the air when, being at different pressures at various levels, it tends to make bodies move with a force proportional to their volume, so electric force existing is a very objectionable description of the condition of the ether, whatever it is, that tends to make bodies move with a force in proportion to their electric charges We know more about the structure of the air than we do about the ether. We know that the structure of the air that causes it to act in this way is that there are more molecules jumping about in each cubic centimetre near the earth than there are at a distance, and we do not know yet what the structure of the ether is that causes it to act in this remarkable way; but even though we'do

not know the nature of the structure, we know some of its effects, by means of which we can measure it, and we can give it a name. Although we know very little indeed about the structure of a piece of stressed india-rubber, yet we can measure the amount of its stress at any yet we can measure the amount or its stress at any place, and can call the india-rubber. In this peculiar condution "stressed india-rubber." As a matter of fact, we know a great deal more about the peculiar condition of the ether that we describe as "electric force." existing than we do about the "stressed india-rubber" and there is every reason to suppose that the structure of the ether is, out of all comparison, more simple than that of india-rubber

When sound-waves travel through the air, they consist of compressions followed by rarefactions, and between them the pressure varies from point to point, so that here we have travelling forward a structure the same as that we nave traveling forward a structure the same as impleted to the air near the earth, and waves of sound might be described as consisting of a succession of positive and negative "volume forces" travelling forward in the air this form of expression would no doubt be objectionable, but still if all we knew about the properties of the air near the earth was that it tended to make bodies move away from the earth with a force proportional to their volume, it is quite likely that this condition of affairs near the earth might have been described as the existence of a "volume force" near the earth, and when it was discovered that this action was due to a medium, the air, it would have been quite natural to describe this state of the air as "volume force" existing in it. and then when waves of sound were observed it would be quite natural that they should be described as waves of "volume force," especially if the only way in which we could detect the presence of these waves was by observing the force exerted on bodies immersed in it, which was proportional to their volumes, and which we happen to know is really due to differences of pressure at neighbouring points in the air. We do not know what is the structure of the ether that causes it to exert force on electrified bodies, but we know of the existence of this property, and when it is in this state we say that "electric force" exists in it, and we have certain ways by which we can detect the existence of "electric force," one of which is the production of an electric current in a conductor, and the consequent electrification of the conductor, and if this is strong enough we can produce an electric spark between it and a neighbouring conductor. When a conductor is suddenly electrified, the structure of the ether which is described as electric force existing in it travels from its neighbourhood through the surrounding ether, and this is described as a wave of electric force travelling through the surrounding ether. It is desirable to be quite clear as to what is meant by the term a wave of electric force. and what we know about it We know that it is a region of ether where its structure is the same as in the neighbourhood of electrified and some other bodies, and owing to which force is exerted on electrified bodies, and electric

currents are produced in conductors.

We may, then, reasonably expect that, if it is possible to electrify a body alternately positively and negatively in rapid succession, there will be produced all round it waves of electric force—that is, if the electric force is propagated by, and is due to, a medium surrounding the electrified body, if electrification is a special state of the medium that fills the space between bodies.

(2) The next question is. How can we reflect these waves? In order to reflect a wave, we must interpose in its way some body that stops it. What sort of bodies stop electric force? Conductors are known to act as complete screens of electric force, so that a large conducting sheet would naturally be suggested as the best way to reflect waves of electric force. Reflection always occurs when there is a change in the nature of the medium, even though the change is not so great as to

* Continued from vol xhii. p. 538 NO. 1123, VOL 44]

stop the wave, and it has long been known that, besides the action of conductors as screens of electric force, different non-conductors act differently in reference to electric force by differing in specific inductive capacity. Hence we might expect non-conductors to reflect these waves, although the reflection would probably not be so intense from them as from conductors. Hence this expection of how to reflect the waves is presty easily solved. We are acting still on the supposition that there is a simultaneously of course their will be no weaves to tree flect, and, consequently, no loops and nodes produced by the interference of the incident and reflected waves.

(3) The third problem is. How can we expect to detect where there are loops and where there are nodes? Recall the effects of electric force. It tends to move electrified bodies If, then, an electrified body were placed in a loop, it would tend to vibrate up and down. This method may possibly be employed at some future time, and it may be part of the cause of photographic actions, for these have recently been conclusively proved to be due to electric force: but the alternations of electric force from positive to negative that have to be employed are so rapid that no body large enough to be easily visible and electrithat no body large enough to be easily visible and electri-fied to a reasonable extent could be expected to move sufficiently to be visibly disturbed. It is possible that we may find some way of detecting the vibrations hereby given to the electrified ions in an electrolyte; and it has recently been stated that waves originated electrically shake the elements in sensitive photographic films sufficiently to cause changes that can be developed. The other action of electric force is to produce an electric current in a conductor and a resultant electrification of the conductor. Two effects due to this action have actually been used to detect the existence of the wave of electric force sent out by a body alternately electrified positively and negatively. One of these is the heating of the conductor by the current Several experimenters have directly or indirectly used this way of detecting the electric force. The other way, which has proved so far the most sensitive of all, has been to use the electrification of the conductor to cause a spark across an air-space This is the method Hertz originally employed, A priori, one would not have expected it to be a delicate method at all. It takes very considerable electric forces to produce visible sparks. On the other hand, the time to produce visible sparss. Of the other hand, the total the force need last in order to produce a spark is something very small indeed, and hitherto it has not been possible to keep up the alternate electrifications for more than a minute fraction of a second, and this is the reason why other apparently more promising methods have failed to be as sensitive as the method of producing sparks. If two conductors be placed very close to one another in such a direction that the electric force another in such a direction that the electric force is in the line joining them, their near surfaces will be oppositely electrified when the electric force acts on them, and we may expect that, if the force be great enough, and the surfaces near enough, an electric spark will pass from one to the other. This is roughly the arrangement used by Hertz to detect whether there are loops and nodes between the originator of the waves and the reflector.

Now arses the problem of how to electrify the body alternately positively and negatively with sufficient rapidity. How rapid is "with sufficient rapidity"? To answer this we must form some estimate of how rapidly we may expect the waves to be propagated. According to Maxwell's theory, they should go at the same rate as light, some 300 million of metres per second, and it is evident that if we are going to test Maxwell's theory we must make provision for sufficiently rapid extric vibrations to give some result if the waves are propagated at this encomous rate. The distance from a mode to a node in half the distance a wave travels during

a vibration. If we can produce vibrations at the rate of 300 million per second, a wave would go I metre during a vibration, so that, with this enormous rate of alternation, the distance from node to node would be 50 cm. We might expect to be able to work on this scale very well. or even on ten times this scale, ie, with alternations at the rate of 30 million per second, and 5 metres from node to node, but hardly on a much larger scale than this It almost takes one's breath away to contemplate the production of vibrations of this enormous rapidity Of course they are very much slower than those of light these latter are more than a million times as rapid; but 300 million per second is enormously more rapid than any audible sound, about a thousand times as fast as the highest audible note. A short bar of metal vibrates longitudinally very fast, but it would have to be about the thousandth of a centimetre long, in order to vibrate at the required rate. It would be almost hopeless by mechanical means to produce electric alternations of this frequency. Fortunately there is an electric method of producing very rapid alternate electrifications Leyden iar is discharged through a wire of small resistance, the self-induction of the current in this wire keeps the current running after the jar is discharged, and re charges it in the opposite direction, to immediately discharge back_again, and so on through a series of olscharge back again, and so on through a series of alternations. This action is quite intelligible on the hypothesis that electrification consists in a strained condition of the ether, which relieves itself by means of the conductor Just as a bent spring or other strained body, when allowed suddenly to relieve itself, relieves itself in a series of vibrations that gradually subside, similarly the strain of the ether relieves itself in a series of gradually subsiding vibrations. If the spring while relieving itself has to overcome frictional resistance, its vibrations will rapidly subside, and if the friction be sufficiently great, it will not vibrate at all, but will gradually subside into its position of equilibrium In the same manner, if the resistance to the relief of the strain of the medium, which is offered by the conducting wire, be great, the vibrations will subside rapidly, and if the resistance of the wire be too great, there will not be any vibrations at all. Of course, quite independently of all frictional and viscous resistances, a vibrating spring, such as a tuning-fork that is producing sound-waves in the air which carry the energy of the fork away from it into the surrounding medium, will gradually vibrate less and less. In the same way, quite independently of the resistance of the conducting wire, we must expect that, if a discharging conductor produces electric waves, its vibrations must gradually subside owing to its energy being gradually transferred to the surrounding medium. As a consequence of this the time that a Leyden jar takes to discharge itself in this way may be very short indeed. It may perform a good many oscillations in this very short time, but then each oscillation takes a very very short time To get some idea of what quantities we are dealing with, consider the rates of oscillation which would give wave-lengths that were short enough to be con-veniently dealt with in laboratories 300 million per second would give us waves one metre long; consider what is meant by 100 million per second. We may get some conception of it by calculating the time corresponding to 100 million seconds It is more than 3 years and 2 months. The pendulum of a clock would have to oscillate 3 years and 2 months before it would have performed as many oscillations as we require to be performed in one second The pendulum of a clock left to itself without weights or springs to drive it, and only given a single impulse, would practically cease to vibrate after it had performed 40 or 50 vibrations, unless it were very heavy, i.e had a great store of energy or were very delicately suspended, and exposed only a small resistance to the air. A light pendulum would be stopped by com-

municating motion to the air after a very few vibrations. insultating instout to the air after a very lew violations. The case of a Leyden jar discharge is more like the case of a mass on a spring than the case of a pendulum, because in the case of the Leyden jar there is nothing quite analogous to the way in which the earth pulls the pendulum : it is the elasticity of the ether that causes the electric currents in the Leyden jar discharge, just as it is the elasticity of the spring that causes the motion of the matter attached to it in the case notion of the matter attended to it in the Case
of a mass vibrating on a spring. It is possible to
push this analogy still further Under what conditions
would the spring vibrate most rapidly? When the spring
was stiff and the mass small. What is meant by a spring being stiff? When a considerable force only bends it a little. This corresponds to a considerable electric force only electrifying the Leyden jar coatings a little, s.e to the Leyden jar having a small capacity. We would consequently expect that the discharge of a Leyden jar with a small capacity would vibrate more rapidly than that of one with a large capacity, and this is the case In order to make a Leyden iar of very small capacity we must have small conducting surfaces as far apart as possible. and two separate plates or knobs do very well. The second condition for rapid vibration was that the mass moved should be small. In the case of electric currents what keeps the current running after the plates have become discharged and recharges them again is the socalled self-induction of the current. It would be well to look upon it as magnetic energy stored up in the ether around the current, but whatever view is taken of it, it evidently corresponds to the mass moved, whose energy keeps it moving after the spring is unbent and rebend the spring again Hence we may conclude that a small self-induction will favour rapidity of oscillation, and this To attain this we must make the distance the current has to run from plate to plate as short as possible. The smaller the plates and the shorter the connecting wire the more rapid the vibrations, in fact, connecting wire the more rapid the viorations, in sact, the rapidity of vibration is directly proportional to the linear dimensions of the system, and for the most rapid wibrations two spherical knobs, one charged positively and the other negatively, and discharging directly from one to the other, have been used Hertz in his original investigations used two plates about 40 cm. square, forming parts of the same plane, and separated by an interval of about 60 cm. Each plate was connected at the centre of the edge next the other plate with a wire about 30 cm. long, and terminating in a small brass knob
These knobs were within 2 or 3 mm. of one another, so
that when one plate was charged positively and the other negatively they discharged to one another in a spark across this gap. An apparatus about this size would produce waves 10 or 12 metres long, and its rate of oscillation would be about 30 million per second As the vibration actually produced by these oscillators seems to be very complex, the rate of oscillation can only be described as "about" so and so In a subsequent investigation Hertz employed two elongated cylinders about 3 cm. long and about 3 cm. in diameter, the remin-ated by knobs about 4 cm. in diameter, and discharging directly into one another. Such an oscillator produces waves from 60 to 70 cm. long, and, consequently, vibra-tions at the rate of between 400 and 500 million per second. Most other experimenters have used oscillators about the same dimensions as Herrz's larger apparatus, as the effects produced are more energetic; but many experiments, especially on refraction, require a smaller wave to be dealt with, unless all the apparatus used be on an enormous scale, such as could not be accommodated in any ordinary laboratory. When we are thus aiming at rapid rates of vibration, it must be recollected that we cannot at the same time expect many vibrations after each impulse. If we have a stiff spring with a small weight arranged so as to give a lot of its energy to the

surrounding medium, we cannot expect to have very surrounding medium, we cannot expect to have 'very much energy to deal with, nor many vibrations, and, as a matter of fact, we find that this is the case. The total duration of a spark of even a large Leyden jar is very small. Lord Rayleigh has recently illustrated this very beautifully by his photographs of failing drops and breaking bubbles. We cannot reasonably expect each spark to have more than from 10 to 20 effective oscillations, so that, even in the case of the slower oscillator, the total duration of the spark is not above a millionth of a second. It is very remarkable that the incandescent air, heated to incandescence by the spark, should cool as rapidly as it does, but there is conclusive evidence that it remains incandescent after the spark proper has ceased, and con-sequently lasts incandescent longer than the millionth of a second. What is seen as the white core of the spark may not last longer than the electric discharge itself certainly does not do so in the case of the comparatively very slowly oscillating sparks that have been analyzed. into their component vibrations by photographing them on a moving plate The incandescent air remaining in the path of such discharge is probably the conducting path through which the oscillating current rushes backwards and forwards Once the air gap has been broken through, the character of the air gap as an opponent of the passage of electricity is completely changed. Before the air gap breaks down, it requires a considerable initial difference of electric pressure to start a current. Once it has been broken down, the electric current oscillates backwards and forwards across the incandescent air gap until the whole difference of electric pressure has subsided, showing that the broken air gap has become a conductor in which even the feeblest electric pressure is able to produce an electric current if this were not so, Leyden jars would not be discharged by a single spark All this is quite in accordance with what we know of air that is, or even has lately been, incandescent . such air conducts under the feeblest electric force All this is most essential to the success of our oscillator Only for this valuable property of air, that it gives way suddenly, and thenceforward offers but a feeble opposition to the rapidly alternating discharge, it would have been almost impossible to start these rapid oscillations If we wish to start a tuning fork vibrating, we must give it a sharp blow it will not do to press its prongs together and then let them go slowly, we must apply a force which is short-lived in comparison with the period of vibration of the fork. It is necessary, then, that the air gap must break down in a time short compared with the rate of oscillation of the discharge, and when this is required to be at the rate of 400 million per second, it is evident how very remarkably suddenly the air gap breaks down. From the experiments themselves it seems as if any even minute roughnesses, dust, &c, on the dis-charging surface, interfered with this rapidity of breakdown, it seems as if the points soluttered out electricity and gradually broke down the air gap, for the vibrations originated are very feeble unless the discharging surfaces are kept highly polished, gilt brass knobs act admirably if kept polished up every ten minutes or so. One of the greatest desiderata in these experiments is some method of making sure that all the sparks should have the same character, and be all good ones.

(To be continued.)

THE ROYAL SOCIETY SELECTED
CANDIDATES.

THE following fifteen candidates were selected on Thursday last (April 30), by the Council of the Royal Society, to be recommended for election into the Society. The ballot will take place on June 4, at 4 p.m. We print with the name of each candidate the statement of his qualifications.

WILLIAM ANDERSON.

V.-P last M.E. M I.C.E. Consulting Engineer, Royal Agricultural Society of England. Popil of the late Sir William Fairbaim, F. R.S. Member of the firm of Messrs Courtney and Stephens, Engineers, of Dublin, from 1855 to 1864 President, in 1863, of the Inst. of Civil Engineers of Feland, to and Stephens, Canadienes, or Jennin, 1990. The stephens of the Society of the Communicated important papers. "On the Theory of Braced Gurden," "The Strength of Railway Bridges of Small Span, and the Cross hearns of Large Hridges," and other subjects. Between 1932 and 1885, communicated many permittens on Sugar Mandacture, in Upper Egypt, by the Sulphurout Acid Process, "Experiments and Observations on the Simsson of Heath y Illowater Pupes," and "Purish the Sulphurout Acid Process," "Experiments and Observations on the Simsson of Heath y Illowater Pupes," and "Purish the Author Purish of the Sulphurout Acid Process, "Experiments and Observations on the Simsson of Heath y Illowater Pupes," and "Purish the Author Purish of Heath y Illowater Pupes, "and "Purish the Author Purish Canadian State of the International Control of Heath and the James Watt Gold Medal of the Into C. F. Author of a Tecture on "The Generation of Steam," hency one of Ibe a Lecture on "The Generation of Steam," hency one of Ibe and the International Control of a Tecture on "The Generation of Steam," hency one of Ibe and the International Control of Lectures delevered at the being the substance of a course of Lectures delivered at the Society of Arts under the "Howard Irust", of a paper on "New Applications of the Mechanical Properties of Cork," communicated as a Lecture to the Royal Institution, and of various papers communicated to the Inst. of Mcchanical Engineers, the Royal Agricultural Society, & Distinguished for the ability with which he has applied his intimate knowledge of the science of heat, and other counsie sciences, to the practical requirements of the engineer.

FREDERICK ORPEN BOWLE, D Sc (Camb).

FREDERICK OFFEN HOWLE, D Sc (Camb), FLLS, F. R.S. F. Regus Professor of Honey in the University of Clasgow Distinguished for his researches in intological and morphological honey. Author (in conjunction Hardward) and the Collaboration of th some Normal and Abnormal Developments of the Oophyte in wome Normal and Nomorma Development of the Normal spirit and Nymeko-ghilous Plant "(Tram Phil Soc Glasg) "The Comparation of the Meritems of Ferns as a Phyl genetic Study "(Annah of Ros., 1889); "On the Morphology of the Leaf of Nepenthes" (tible); "On Antithetic as distinct from Leaf of Nepenthes" (tible); "On Antithetic as distinct from John Monitors (1912.); "On Antinetic as distinct from Homologous Alternation of Generations in Plants" (bids, 1890) Translator (in conjunction with Dr. D. H. Scott) of "Comparative Anatomy of the Phanerogams and Ferns," by Anton de Bary (Clarendon Press, 1884).

SIR JOHN CONROY, Bart, M A.,

F.C.S. Lecture on Physics and Chemstry, Keble College, Oxford. An aamdoust Student of Experimental Science, and suther of the following papers—"On the Devoted of Calcium student of the following Chem. Soc., 1873)." On the Points at the Points of Calcium of Light by Journal of Proc. Roy. Soc., 1896). "Absorption Spectra of Indian" (Proc. Roy. Soc., 1896). "On the Light reflected by Poissaum Permanganase" (Paul. Mag., 1879): "Experiments on Heatin the Visible Spectrum" (Paul. Mag., 1879): "Experiments on Metallic Reflexion" (Pecc. Roy. Soc., 1971, 1879), 1889.

DANIEL JOHN CUNNINGHAM, M D (Edin), M.D. (Dublin), F.R.C.S.L., F.R.S.E., F.Z.S., Professor of Anatomy, University of Dublin Distinguished both as a

NO. 1127, VOL. 44

teacher and original inquirer. Examiner in Anatomy in the Universities of London, Edinburgh, and Disbin. Member of Council, Royal Irish Academy. Vice-Pres Zoological Society, Ireland. Vice-Pres, Anatomical Society of Great Britain and Ireland Author of numerous anatomical memoirs in journals and publications of scientific societies. More especially may be and publications of scientific societies. More especially may be mentioned—"Report on the Anatomy of the Marsupulia," (Challenger Report, Part 16),..." The Lumbar Curve in Man the Royal Irn's Anatemy, 1886,..." The Spiral Nervous System of the Porpone and Dolphin." (Gront. Anat. Physiol., 1876). Author of a Text-book of Irractical Anatomy.

GEORGE MERCER DAWSON, D Sc.

GEORGE MERCER DAWSON, D. Sc.,
F. G.S., A. R. S. M., F. R. S. C. Assistant Director, Geological
Survey of Canada. Much important and valuable work, more
expecually in geology and shinology, a. in the following summary
statement: Daring his bittere they trugged in working out the
varvey (Canada, has been rehely) trugged in working out the
Placed in charge of the Vision Expedition, 1887. Author of
memorant papers, chiefly geological, but including geographical,
ethnological, and other observations, published in the Quart,
Journ Geol. Doe, I rans Key Doe Canada, Canadan Naturu
Jour, &c. These deal more especially with the superficial
and a their misconnic organisms. Author of fifteen general
and after misconnic organisms. Author of fifteen general geology of the ragions explored, but some describs. Poraminifera and inther microscopic organisms, Author of fifteen reports published by the Geological Survey of Canada, and joint author (with Dr Selwyn) of a Descriptive Section of the Physical Geography and Geology of Canada, and (with Dr W F Tolme) of Comparative Vocabularies of the Indian Tribes of British Columbia

EDWIN BAILEY ELLIOTT, MA,

Fellow of Queen's College, Oxford Vice President of the London Mathematical Society Mathematical Lecturer of Queen's and Corpus Christi Colleges Distinguished as a Queen's and Corpus Christ Colleges Distinguished at a Mathematican and original investigator in various branches of mathematical research. Author of the following pipers "clienterilation of Prevot and Linduler's Thoorem in Chances." (Ed. Timer, vol. xxxv); "On Normals to Livelopes, "Gibbs, "Christian Colleges, "Christian Christian, "District Christian," (Ed. Timer, vol. xxxv); "On Normals to Livelopes, "Christian Christian, "District Christian, "District Christian, "District Christian, "Normalican Christian," "Mathighe Fruilianam Integrabs," (Ind., vol. xv., p. 147); "Multiple Fruilianam integrabs," (Ind., vol. xv., p. 147), "Multiple Fruilianam with One Degree of Freedom," (Mat., of Math., vol. vv., p. 35), "The Linear Parint Inferential Equations of Systems with One Degree of Freedom," (Mat., of Math., vol. vv., p. 35), "The Linear Parint Inferential Equations and State Christian, "District Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain Learn District Linear District Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain Learn District Linear District Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian Christian," (Proc. vol. 147), "On the Interchange of the Variables in certain control of the Christian Christian xviii, p. 142), "On the Interchange of the Variables in certain Linear Differential Operators" (Abstract, Roy Soc. Proc, vol xiv., p. 338 [ordered to be printed in the Phil Trans]), and eighteen other paper, printed in the London Mathematical Society's Proceedings and elsewhere between the years 1875 and rSon.

PERCY FARADAY FRANKLAND, B Sc.

ARSM, PhD Professor of Chemistry Formerly Senior Demonstrator in the Chemical Laboratory of the Normal Schools Demonstrator in the Chemical Laboratory of the Normal Schools of Science, South Kensington Author of upwards of twenty original papers in the Phil Trans and Proc Roy Soc, in the Jonnals of the Chem Soc, the Soc of Chem Industry, &c. Known for his researches on Bacteriology and on the Chemical Aspects of Fermentation.

PERCY C GILCHRIST.

A R S M Metallurgat Datinguished as a Metallurgial, expecually in connection with the manifactifie of ron and steel In association with the late Mr. S. C. Thoms he greatly added to the control of the c ARSM Metallurgist Distinguished as a Metallurgist, and elsewhere

F.I.C President of the Society of Chemical Industry, W.-P. Chem. Soc. Disamguished technical chemist and inventor Has NO. 1123, VOL. 44]

made important additions to chemical industrial processes and made important additions to chemical industrial processes and products, especially with reference to the sital industry, having products, as the products, and the products of development of the ammonia soda process of alkali manufacture into England Author of various papers in Rept. Brit Assoc., Journ. Soc. Chem Ind.

WILLIAM NAPIER SHAW, M A.,

Fellow of Emmanual College, Cambridge Was nominated by Lord Rayleigh as one of the Demonstrators of Physics in the Cavendish Laboratory at Cambridge. He held that position from 1880 to 1887, and he has since continued his connection with the Laboratory as University Lecturer in Physics. His knowledge of the manner in which the teaching of Physics is knowledge of the manner in which the teaching of Physics is conducted in the great German Universities (acquired at Berlin under Helmholtz) enabled him to bear an important part in the organization of the laboratory. A considerable part of the suc-cess of the Cambridge School of Physics is due to his exertions, cess of the Cambridge School of Physics is due to his exertions, backed by his knowledge of Physics. Author of immerous backed by his knowledge of Physics. Author of immerous of notice—"Practical Physics" (jointly with Mr. Glazdrood), Longmans, 1883, "Practical Work in the Cawendh Laboratory," Unsternity Press, 1860, "Faraday's Law of Electrolysis "Electrolysis" and "Pyromater," "Engy: Brill," 1"On Vapermeters," & C., Rept. to the Meteorol. Council, 1884, "On Higgmenter Methods, Part.," "Rept. to the Meteorol. Council, printed in Phil Trans

SILVANUS PHILLIPS THOMPSON, D Sc (Lond).

SILVANUS PHILLIPS TROMPSON, D Sc (Lond), Principal and Professor of Physics in the City and Gould of I ondon Technical College, Finshury; formerly Professor of I ondon Technical College, Finshury; formerly Professor of I ondon Technical College, Principal College, Bristol, Author of many papers published in the Proceedings, &c., Royal Sonetty, Physical Society, institution of Electrical Engineers, Society, of Theory of the Magnetic Balance "(Proc. Roy. Soc., 1884); "Electro-deposition of Alloys" (Wald., 1887), ""Opacity of Tourishine Crystal", (Ind., 1881), "The Measung of the Constant and Crystal", (Ind., 1881), "The Measung of the Constant and Crystal", (Ind., 1881), "The Measung of the Constant and Crystal", (Ind., 1881), "The Measung of the Constant of Mag., 1883), "Development of the Mercural Air Panja" (Journ Soc., 1884), "Development of the Mercural Air Panja" (Journ Soc., 1884), "New York (Indiano Control Constant of Con more particularly in its experimental and technical aspects.

THOMAS HENRY TIZARD, Staff-Commander, R.N.,

FR.GS. Distinguished as a Hydrographical Surveyor and Marine Meteorologist. Has been employed for 25 years in the Naval Surveying Service. In China, Mediterranean, and Red Seas, 1862-72. Senior Assastant-Surveyor in the Challenge Seas, 1860-72 Senor Amstant-Surveyor in the Chalinger Lapedition, 1879-70. Prepared the reports on the sea tem-lapedition, 1879-70. Prepared the reports on the sea tem-taged the report of the reports of the sea temperature of the season o

THE ENDOWMENT OF RESEARCH IN FRANCE

A T the meeting of the Paris Academy of Sciences on April 27, the Secretary read the following extract from the will of the late M. Cahours:

"I have frequently had the opportunity of observing, in the course of my scientific career, that many young men, distribution of the course of my scientific career, as we themselves obliged to abandon it because at the beginning they found no effections help which provided them with the first necessities of life and allowed them to devote themselves exclusively to scientific studies

"With the object of encouraging such young workers, who for the want of sufficient resources find themselves powerless to finish works in course of execution, and in remembrance of my heloved children, who also would walk in a scientific path at the moment when death takes me from them, I bequeath to the Academy of Sciences, which has done me the honour to admit me into its fraternity, a sum of one hundred thousand francs "I desire that the interest of this sum may be distributed

every year by way of encouragement to any young men who

more particularly by chemical researches

"In order to assure this preference, independently of the express recommendation that I make here to my successors, I wash that, during at least venty-five years after the commencement of the interest payable to the Academy, three members at least of the Chemistry Section may take part each year in a Commission of five members charged by the Academy to distinct the property of the payable the prizes. I express further the formal desire that this commission on new members charged by the Academy to distinct the prices. I express further the formal desire that this choice should fall, as far as possible, on young men without fortune not having aslaried offices, and who, from the want of a sufficient situation, would find themselves without the possibility of following up their researches.

of following up their researches.

"These pecuniary encouragements ought to be given during several years to the same young men, if the Commission thinks that their productions have a value which permiss such a favour "Nevertheless, in order that the largest number of young

aveverinciess, in order that the largest number of young workers may participate in the legacy I institute, I desire that the encouragements may cease at the time when the young seasants who have enjoyed them obtain sufficiently remunerative positions

M Janssen then made the following remarks -

"The legacy which has been made to the Academy, by our very eminent and very regretted confield, appears to me to have considerable import not only by its importance, but especially by the way that it opens, and the example that it affords, to all those who hereafter may desire to encourage the sciences by their

"M Cahours, whose sure judgment and long experience enabled him to know the most urgent necessities of science, had, like most of us, become convinced of the necessity of introducing a new form in the institution of scientific re-

"Our prizes will always continue to meet a great and noble accessity, their value, the difficulty of obtaining them, and the kédat they take from the illustriousness of the body which awards them, will make them always the highest and most

envised of recompenses.

"But the value, also, of the works it is necessary to produce in order to lay claim to them prohibits the research to beginners. It is a field that is only accessible to maured talents

"But, besides those savants who have already an assured career, there are many young men endowed with precious aptitudes, and directed by their inclination to pure science, but turned very often from this envied career by the difficulties of existence, and taking with regret a direction giving more immediate results. And yet, how many among them possess talents which, if well cultivated, might do honour and good to science !

"We must say, however, that it is in leaving their studies that those who wish to devote themselves to pure science experience the most difficult trials, and these difficulties are increased every day by the very rapid advance of the engencies of lete

"We must find a prompt remedy for this state of things of we do not wish to see the end of the recruitment of science. NO TIME VOL 447

"This truth, however, is beginning to be generally felt. The Government has already created institutions, scholarships, and encouragements, which partly meet the necessity. Some generous donors are also working in this manuer. I will mention especonformations a hall is at this moment being built, where whose intentions a nail is at this moment being built, where young men, having shown distinguished aptitudes for high administration, the bar, or history, will receive for three years all the means of carrying on high and peaceful studies.

"Let us say, then, plainly, and in speaking thus we only feebly echo the expressions of the most illustrious members of by Cahours that it is by following the way so nobly opened by Cahours that the interests and prospects of science will be most efficaciously served."

NOTES

A SPECIAL meeting of the Physical Society of London will be held at Cambridge on Saturday, May o The members will leave Liverpool Street at 11 a.m., and on arrival at Cambridge will become the guests of the Cambridge members meeting will be held in the Cavendish Laboratory at 2 30 The following communications will be read some experiments on the electric discharge in vacuum tubes, by Prof. J Thomson, F R S.; some experiments on ionic velocities. by Mr W C D Whetham, on the resistance of some mercury standards, by Mr R T Glazebrook, F R S , on an apparatus for measuring the compressibility of liquids, by Mr S Skinner, some measurements with the pneumatic hridge, by Mr W N Shaw After the meeting members will have an opportunity of seeing the Cavendish Laboratory and other University Laboratories.

THE annual meeting of the Iron and Steel Institute began vesterday, and will continue to day and to morrow. It is being held as usual at the Institution of Civil Engineers in Great George Street.

A VALUABLE bequest has been made to the Department of Science and Art by the late Miss Marshall, of 02 Warwick Gardens, Kensington In addition to a large number of scientific books and instruments which are left for the use of students. a sum of £1000 is bequeathed for the founding of scholarships, or for application in any other way that may be considered best for the advancement of biological science

THE Queen has approved the appointment of Lord Derby to be Chancellor of the University of Lundon, in the room of the late Lord Granville.

THE death of Prof Joseph Leidy, in his sixty eighth year, is announced. He was Professor of Anatomy in the University of Penusylvania and of Natural History in Swarthmore College . President of the Academy of Natural Sciences of Philadelphia; and Director of the Department of Biology in the University. In a future number we shall give some account of his services to science

A REUTER's telegram from New York, dated May I, announces the death, at Berkeley, California, of Prof. John Le Conte. brother of Mr. Joseph Le Conte, formerly professor of geology and natural history in the University of California.

WE regret to have to announce the death of Captain Cecilio Pujazon, the Director of the Marine Observatory of San Fernando, near Cadiz He died on April 15, in his fifty-seventh year. Captain Pujazon was well known to the members of the Eclipse Expedition of 1870, who formed the Cadiz party. He came to London to the Conference on Marine Meteorology in 1874

In answer to a question put by Mr H. Fowler in the House of Commons on Monday, Sir W. Hart Dyke said that from the returns already received, in answer to a circular issued by the Science and Art Department at the end of March last, it appeared that of the fifty county councils and sixty county boroughs in England, axteen of the former and twenty-five of the latter had already decided to apply the whole of their share of the residue under the Local Taxation (Customs and Exeise) Act of 1890 to science and art and technical education Nine county councils and two county boroughs had made grants varying from "nearly the whole" to a smaller proportion of their share to the same purpose Twelve county councils and seven county boroughs had the matter under consideration , that as to say, they had appointed committees, and in many cases the committees had recommended the allocation of the whole or the greater part of the residue fund to technical instruction, but their reports had not yet been confirmed by the county or borough councils With regard to Wales, the question was complicated by the fact that the Welsh Intermediate Education Act included seehnical instruction, but it appeared that four county councils and one county borough had applied the whole of their share of the residue under the Intermediate Education Act: while two county councils and one county borough had divided their quota between that Act and the Technical Instruction Act. The remaining six county councils had either made no return, or else had the matter under consideration.

THE Council of University College, Bangor, having resolved to make provision in the physical department (Prof. A Gray) for the study of applied electricity, an 8 horse-power (nominal) compound engine, working up to 24 horse-power, has just been installed by Mesars Robey and Co , Lincoln On Saturday last a satisfactory trial of the engine and boiler was made. The equipment includes a special educational Victoria dynamo (capable of being converted at will into a shunt, compound-wound, or series dynamo, without impairing its usefulness for general work), by the Brush Electrical Engineering Co., an alternating dynamo, and a large secondary battery The electrical measuring instruments are of the latest design, and include a fine composite balance, and electrostatic voltmeter of Sir William Thomson's invention. The equipment forms a valuable addition to the resources of the College for the teaching of pure and applied physical science, and will render it possible to give a very complete course of instruction in electrical engineering, as well as in the general theory of electricity.

THE Philosophical Society of Berlin offers a prize of 1000 marks for the best essay on the relation of philosophy to the emplrical science of nature The essays may be written in German, French, English, or Latin, and must be sent in before April 1. 180.

THE Italian Meteorological Society has celebrated its twentyfish anniversary by erecting a memoral table in the mediaval castle of Turin. The founder of the Society, Father Densa, and various notabilities and hidse were present. Father Densa gave a riment of the history of the Society, which now possesses no less than 250 observatores and stations. The cremony was terminated by the transmission of a telegram to the King, 34 Honorary Freident of the Society.

True Chief Signal Officer of the United States has published Part III. of "Bibliography of Mecorology," comprung tutter relating to the general motions of the atmosphere, or "winds," while the important divasion of "storms " is being prepared for inne as Part IV. The present volume, like its predocessors, is althographic reproduction of a copy prepared by means of a type-writer, as funds were not forthcoming for printing the work, and it constains stutial of zooo titles of books and sparen daming from the origin of printing to the close of 1881, with a suppliment to the close of 1889, and an author index. The work is quite unique, and will be an invaluable aid to the study of the subject treated of

NO. 1123, VOL. 44]

An account of the Birmingham School of Medicine, written originally for the moreasian of those members of the medical profession who attended the Birmingham meeting of the British Association in 1850, has now been published separately. The authors are Dr. B. C. A. Windle and Mr. W. Hillhouse. Their mentions to show—and thus they do most effectually—that the centre of the Midland district possesses one of the best equipped schools of medicine in the provinces. The interest of the descriptions is greatly increased by reproductions of some photographs.

A First and Game Communion, taking evidence on behalf of the Ontation Government, has received many complaints as to the destruction of deer and other depredations by wolves, and all the winnesses agree that the present bounty of £1 paut for each wolf killed should be rased to £2 100. or £3. It has also been shown that, if the game laws are not more strictly coforced, many birds and far bearing animals will probably be exterminated.

THE preliminary returns of the recent census operations in India show that the population in British territory is 220,400,000, as against 198,655,600 in the former census, an increase of nearly 22,000,000. The Feudatory States, omitting incomplete returns, which may be taken at about 90,000, have a population of 61,410,000, making a total of 281,900,000, as against 250,700,000 for the same areas at the last census The returns give Bombay 805,000, Madras 440,000, Calcutta municipal area and port 674,000, and including the suburbs Howrsh and Bally, 969,000. At the last census the total for the same area was 847,000 Calcutta municipal area shows an increase of 92,000, and Howrah and Bally an increase of 24,000. The returns from Burmah show that the population of the whole country, excluding the Shan States, is 7,507,063, or 48 8 persons to the square mile. The population of Lower Burmah alone 15 4,526,432, or an increase of about 700,000 since 1881

THE Boston Society of Natural History has usued a pamphlet announcing the completion of the general plans for the formation of zoological gardens and aquama in Boston, and appealing to the American public for support. The pamphlet is prettily printed and illustrated, and sets forth very effectively the arguments which may be advanced in favour of the scheme.

The new number of the Journal of the Royal Horticultural Society contains a full report of the Dahlin Conference, held at the Chiawuck Gardens on September 23 lad, and of the Grape Conference, held in the same Gardens on September 24. The number also contains valuable papers on various other subjects interesting to horticulturals.

THE Trustees of the Indian Museum, Calcuta, have issued an interesting and mixercitors; Report, by Mr. b. C. Cotes, on the locust of North Western India (Aerailum pregramus). The Report sums up the results of an investigation conducted in the entomological section of the Museum It seems to be stablished that most of the flights of this locust leuse from the region of sand hills in Western Rajpatana. Others, however, invade Indian from breefing grounds which probably he along the Sultination from the region of the Sultination of the Sultina

THE New Zealand Journal of Science, the publication of which was suspended in 1885, has been revived. The first two numbers of the new issue have been sent to us, and if the same general level of excellence can be maintained in faiture numbers, there ought to be no doubt as to the success of the enterprise. The following are among the papers: on the history of the Kiws, by Prof. T. J. Parker: on the breeding habits of the European sparrow in New Zealand, by T. W Kirk , the humblebee in New Zealand, by G M. Thomson ; some notes on the occurrence of the trap door spider at Lyttelton, by R M. Laing: on the discovery of the nickel-iron alloy Awarute, by Prof. G. H. F Ulrich.

In the paper on the humble-bee in New Zealand, Mr. Thomson says that, wishing to find how far these insects are adapting themselves to new flowers in the colony, he has for a considershle time kept a record of the flowers they visit and of those they leave alone. He has noticed them on many species of introduced plants which they never appear to visit in Europe, They seldom approach white flowers, and, with two exceptions, he has never heard of their visiting the flowers of indigenous plants The exceptions are Fuchnia excepticata and the Ngato (Myotorum latum).

MESSES. R. ETHERIDGE, JUN, AND MR A. SIDNEY OLLIFF have produced in common a paper which forms a valuable addition to the Memoirs of the Geological Survey of New South Wales. The title is "The Mesozoic and Tertiary Insects of New South Wales."

MESSES BAILUIRE, TINDAUL, AND COX publish a second edition of Dr Thomas Dutton's practical treatise on "Sea-Sickness." Sensible readers will at once be favourably impressed by the author's statement that there is "no absolute specific " for this distressing malady

MESSRs CASSELL AND Co have issued Part 21 of their "New Popular Educator," which will be completed in 48 parts Besides illustrations in the text, there is a carefully prepared page representing coloured reactions characteristic of certain

MR. T. H. CORNISH, of Penzance, has a note in the current number of the Zoologist on some remarkably large catches of fish on the Cornish coast On March 18 last, 12,000 grey mullet, Mugil capito, were captured, by means of a draw seine. by the fishermen of Senneu Cove, at Whiteand Buy, Land's End The fish were of fine quality, one being brought to Mr Cornish which measured 2 feet in length, I foot 3 inches in girth, and weighed 6 pounds 10 ounces. On the 31st of the same month a Lowestoft mackerel driver, fishing some leagues outh-west of the Lizard, took 48,000 mackerel No such catch of mackerel, for one night's fishing, had ever been heard of before it Penzance, and what makes it more extraordinary, says Mr Cornish, is that it should have taken place in March, when the atches usually average a few hundreds only. Later on in the season, in the fishing west of Scilly, 20,000 to 25,000 is regarded is a heavy catch. The catch sold for £ 160

WITH reference to our note (vol. xliii p 521) on an award made by the Japanese Government to Dr. Shohes Tanaka for "the invention of a new musical instrument," Mr. J. W Goundry, of Gosforth, Newcastle, writes to us that over twenty years ago he patented an arrangement for giving enharmonic intervals in all keys on the ordinary unaltered keyboard, and hat he has had both an organ of 31, and a harmonium of 36, sounds per octave, playing Bach's fngues and Handel's choruses, &c , on the system He claims that, although his patents were very crude and imperfect, they contain at least the germ of a complete solution of the problem of reconciling just intonation with the ordinary manual. "They embody a system of sounds." he says. " which I believe to be theoretically the truest and practically the simplest possible, and which has nowhere else been described "

AMMONIUM sulphovanadate, (NH4) VS4, has been isolated in large crystals by Drs Kruss and Ohnmais, and an account of NO. 1123. VOL. 44]

sulpho salts of vanadium, will be found in the latest number of Liebro's Annalen It is well known that when ammoniacalsolutions of vansdates are treated with sulphuretted hydrogen a magnificent purple colouration is produced, presumably due to the formation of sulpho-salis. It has not been found possible, however, to obtain such salts by crystallization in pacuo. The method of obtaining the ammonium salt now described is as follows -A stream of sulphuretted hydrogen is led into an icccold saturated solution of ammonium metavanadate, NH, VO, in the strongest ammonia. The immediate effect is to produce the violet-red colour, but the colouration soon disappears and a brown solid is precipitated On continuing the passage of the gas this precipitate slowly redissolves with production again of the deep violet colour. When the re solution of the precipitate is almost complete the liquid is filtered, and sulphureited hydrogen again led through the solution. In a short time crystals commence to separate, when the current of gas is stopped and the liquid left to crystallize in a closed vessel. The crystals thus obtained consist of opaque rhombic prisms very much resembling in appearance those of potassium permanganate. The faces are very brilliant and reflect a steel bluish-violet colour with a greenish tint when the reflection is received at a certain angle. They may be washed with absolute alcohol and afterwards with ether, and finally dried in vacuo. The mother liquors from the first crystallizations deposit magnificent crystals on being allowed to stand some weeks. The substance may be much more quickly obtained and in larger quantity by substituting either potassium or sodium vanadates for the ammonium vanadate used in the above mode of preparation, as these salts are much more soluble in ammonia than ammonium vanadnte. It is somewhat remarkable that in this case pure ammonium sulphovannulate should be obtained, no potassium or sodium sulpho salts being ever found in the product. The crystals of ninmonium sulphovanadate are permanent in dry air, but are slowly decomposed with evolution of sulphuretted hydrogen in most air. They are readily soluble in water, forming a solution which is coloured intensely violet even when very dilute. A solution containing only one part of the salt in 100,000 parts of water still pussesses a benutiful rose red colour. After a short time this solution decomposes, sulphuretted hydrogen being liberated and the colour changing to brown When a freshly prepared solution is added to a solution of a salt of the alkaline earthy metals, no precipitate is produced, owing to the solubility of the sulphovanadates of these metals. But in the case of calcium n remarkable deepening of the violet colour is produced. If, for instance, a little calcium chloride is added to a dilute solution possessing a just perceptible rose tint, the colour becomes immediately deep violet, owing to the extreme inctorial power of the calcium salt.

In our note in vol xliii p 592, upon the preparation among other silicon compounds of ailicon chloro-tribromide, SiClBra by M Besson, it was stated that this substance had not been hitherto prepared We wish to correct this statement. Silicon chloro tribromide was prepared by Prof. Emerson Reynolds in 1887, and a descriptive note of the work was given in NATURE nt the time (vol. xxxvi. p. 137).

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (Macacus rhesus ?) from India, presented by Mrs. Emily Palmer, two Brazilian Caracaras (Polyborus brankensis) from Terra del Fuego, a Turkey Buzzard (Cathastes aura) from the Fulkland Islands, presented by Mr. F. E Cobb, C.M.Z S ; two Herring Gulls (Larus argentatus), British, presented by Mrs. Attenborough; a Pine Grosbeak (Penicola, enuclentor), British, presented by Mr. W. H St Quantin; a Bennett's Wallaby (Halmaturus bennetts &) from Tasmania, two Diamond Snakes (Merelia stulpter) from their work, which also includes the preparation of several other Australia, deposited, two Tasmanian Wolves (Thylacinus

cynocephalus & Q), three Ursine Dasyures (Dasyurus ursinus & 9 9) from Tasmania, two Brush Turkeva (Talegalla lathami & V), four Australian Wild Ducks (Anas superciliesa) from Australia, received in exchange : a Black Lemnr (Lemur macaco), two Persian Gazelles (Gazella subrutturesa), born in the Gardens

THE INSTITUTION OF MECHANICAL ENGINEERS.

O'N the evening of Thursday and Frinds of last week, the post of the state of the Institution of Mechanical English that and the last match the Institution of Mechanical English Institution, occupylishers and the Institution of the Institution of the Institution of the Institution of Mechanical Institution of the Institution of There were two items on the programme—namely, a paper on Lancashire boilers, and a further report from the Research Committee on Marine Engine Trials The discussion of the latter occupied so much time that the holler paper had to he shelved until next

The latest steamer upon which the Marine Engine Research The latest steamer upon which the Marine Engine Research Commission has been experimentally at eargor weed among the Hartlepool, and is a good modern example of what can be done in fuel economy with triple expansion engines when high speed is not aimed at. This latest report of the Committee should in the committee of the commi of the Meteor, Fust Yama, and the Colchester came out at not of the Medeer, Puss Yama, and the Colchester came out at not less than 2 pounds of coal per indicated horse-power per hour —the Colchester's consumption being nearly 3 pounds per hour—it was said, by those who had never believed in the claims of marine engineers, that the bubble was pricked by trial made by competent and unbassed persons. It is true the economical form of steam motor, for there can be no doubt that the engines of that vestel have given off on trial one unt of power per hour for less than the pound and a half of coal, and we have no reason to think that the 138 pound shown on the chief engineer's independent trial is not a fair average for sea running when the disturbing element of measuring lanks is omitted The Jona is a well decked vestel, built in 1859. She has

triple expansion engines on three cranks, working a single screw erpie expansion engines on tincre cranks, working a single screw lie vessel is 275 feet long, 37 3 feet wide, and 19 feet deep In the hold. Her moulded depth is 21 feet to inches, and her coefficient of fineness is 0 765. She has a cellular bottom. Her mean draught in dock before trial was 20 feet 8 inches, but she mean draught in dock before trial was 20 feet 8 inches, but she rose half an inch in sail water, the displacement being 4430 tons. The engines had been freshly overhauled The trial took place off the east coast, between Robin Hood Bay and Great Yarmouth. The weather was fine throughout. The engines Great Varmonth. The weather was fine throughout. The engines are ripple compound surface conficiently. The vyinders are but are replected to the control of are triple compound surface condensing. The cylinders are p

area through the tubes is 18'3 square feet, and the area acro the funnel 30 7 square feet. A notable feature about this vessel is that the bullers are worked on forced draught; or rather there is is that the Suders are worked on forced draught; or rather there is an faor supplying at toth fers, for a pressure equal to only 0'17, onch of water in the sak pats hardly fulfils the popular notion of forced draught. The attemfor driving flexian engane was supplied from the donkey botter, and therefore the measurement of quantities in the performance that The matter is not one of great importance—the power to drive the fan not being, person, but we question whether it is strictly affected that the same that the district of the power for the propelling engues, but we question whether it is strictly affected that the same tha main supply The boilers in this ship have an extra-ordinarily large proportion of tube surface as compared to the grate surface, and this would be likely to lead to an insufficiency grate suriace, and this would be likely to lead to an insufficiency of draught were the lighter specific gravity of the chumery gates alone depended upon II, therefore, the and of the fan last of the control of the c before the boiler, but not more so than the feed pumps; all boilers, however, must have feed-pumps, while comparatively few have fan-engines. If ever it comes to be that fan engines are simpost as many markets. almost as much matters of course as feed pumps, it will be convenient to class the former with the engine, but until then it is as well to estimate the steam required for forced draught purposes by itself, still it should be taken into account.

The air from the fans is taken to the furnace through gridlron valves, which close automatically when the furnace door is opened, so as to prevent a rush of flame into the stokehold. A openico, so as to prevent a rush of name into the stockehold. As small jet of ar is also admitted through the wet end of the boiler back by a passage made for the parpose. In this way there are two streams of are which meet in the combistion-chamber. There is also a hanging bridge attached to the back the plate, and depending into the flame box at the back of the put the cylindrical fities of modern high-pressure holders on an equality, in the matter of combastion, with the rectangular furnaces of the comfortable low pressure days of the past generation of marine engineers. At the same time we must not forget that a large amount of fuel burnt on a small gratte requires a large combustion chamber. It is the volume of gases evolved which has to be considered. It should be stated that the arrangement for forced draught was designed by Mr J. R. Fothergill, of Hartlepool, engineer superintendent to the firm owning the ship.

	Tons
Engines alone	94 92
Shafting, tunnel bearings, and propeller	26 59
Engine room auxiliaries, including donkeys,	
pipes, platforms, ladders, and graings	12 16

are the means .--

Chimney temperatures were read every half hour by a mercury thermometer and by two Murne pyrometers at 30 feet above the furnace bars. The readings of the three instruments agreed, the average temperature being 452" F It was a pity that the readings were taken so far from the fires, it being desirable to know the heat of the products of combustion immediately after leaving the heating surface of the booler. The arrangement, however, was unavoidable, owing to the exigencies of running the ship on her voyage. The measurement of the feed was the ship on her voyage The measurement of the feed was carried out by means of two tanks in the usual way. An effort was made to determine the quantity of water brought over un-evaporated, by the draught of steam. This was done by taking samples of condensed steam from the steam pipe and samples of botter water, and analyzing them to ascertain the percentage of pairs of analyses male, it was estimated that there was 2 87 per cent of inevaporated boiler water in the condensed steam. If this were the case with hoilers so easily driven as those of the Iona, where there could hardly have heen any semblance of " as the term is understood by engineers, the quantity of water brought over in small and hardly driven boilers must be enormous It is a point of the greatest importance in steam-engine economy, and we trust Prof Kennedy will pursue his investigations in this direction. It also came out during the discussion that the stop valve, or throttle valve, was very much closed during the trial, a fact which should still further have reduced the chance of unevaporated water finding its way into the engines

the engines Indicator diagrams were taken every half-hour during the trial, and an average set is attached to the report. The power was very evenly distributed between the three cylinders, showing good design of the engines. The total indicated horse power was 645. Diagrams were also taken from the air and circulating pumps. For these interesting and valuable details we lating pumps For these interesting and valuable details we must refer our readers to the paper itself, as we are unable to

reproduce the diagrams

The following are some of the chief elements of the trial:

Efficiency of boiler 69'2 per cent. engine 17 1 engine and boiler Mean speed of vessel during trial 8 6 knots per hour

A long discussion, occupying both evenings of the meeting A long discussion, occupying both cramings of the feelings followed the reading of the paper, but our account has already extended to such a length that we cannot give a report of it. extended to such a length that we cannot give a report of it, Perhaps the most interesting point raised was in connection with the closing of the chimney damper, which it appeared was only that the such as the such as the such as the such as the that in this way heat was prevented from escaping up the chimney. It is difficult to account for such an effect, excepting perhaps to some firfulng extent due to minor causes, but several engineers whose opinion is worthy of respect testified that such was the effect in practice. One would think that the escape of heat by the chimney would be governed by the volume of escaping products of combustion with a chimney of any reasonable ornes aren

CAMBRIGG — The Irst Clerk Maxwell Scholarship, for re-search in Experimental Physics, has been awarded to W.

Mr. H. J. Mackinder, the Reader in Geography at Oxford, as
lecture for the Teachers' Training Syndicate on "The Teaching of Geography," on May 30.

The annual dinner of the Philosophical Society was held in

the Combination Room of St John's College on May 2, Prof. G Darwin in the chair

DUBLIN —Sir Robert Ball begins on Wednesday, the 13th inst, a course of lectures on "The Theory of Screws," in Trinity College, Dublin

SCIENTIFIC SERIALS

THE Quarterty Journal of Microscopical Science for March ontains—On a new species of Phymosoma, with a synopsis of the genus, and some account of its geographical distribution, by Arthur F Shipley (Plate xi) The new species, P weldon, was found by Prof Weldon at Bimmi Island, the Bahamas, it has no trace of hooks on the introvert ; there are two retractors. A synopsis of the twenty seven species now known is given, but seventeen species are described in Selenka's monograph on but seventeen species are cescribed in Scienka's monograph of the Sipaneulude. At to the geographical distribution, seventeen species are found in the Malay Archipelago, of which thriteen are endemic, five are found in the Red Ses, four in the Mauri tius, and three are found in the West Indies, but P. fourents is found only in the Hergen Fiord—On the British species of Crisia, by Sidney F. Harmer (Plate xii.). The author thinks that the ovicells furnish sausfactory specific characters; the that the ovicells turnish satisfactory specific characters; the aperture in the ovicell is sho an important character. Specific disgnoses of C deniculata, Link., C, chirman, Linn., C acuteata, Hasv., and C ramona, n. sp, are given. Notes are given of the habit of the Zoarium at different seasons, on are given of the habit of the Zoarum at different seasons, on the mode of branching, and on the breeding-times—The later larval development of Amphioxas, by Arthur Willey (Plate-stut-zv). The author again visited Messans, in the summer of 1890, to complete his studies on the development of the strial chamber of Amphioxas. As a possible explanation of the asymmetry of the larva, Willey thisles that it can be traced ultimately to the adaptive forward extensips of the notochord, being thus a purely ontogenetic prenomenen; the club shaped gland is shown to be a modified gill-slit.—On the structure of two new genera of earthworms belonging to the Eudrilder, and some remarks on Nemertodrilus, by Frank E. Beddard (Plates xvi.-xx). Hyperiodrilus ofricanus, n. gen. and vp., and Helio-drilus lagosenus, n. gen. and sp., found in a Ward case from Lagos, at Kew Gardens.

Thus only article of general interest in the Nuovo Giernale Bolanno Italiano for April 12 a note on the sigmatic disk of Vinca major, Ny By, M. Philotono, In the reports of the Italian Botaninal Society are short papers by Str. Baccamin on the secretory system of the Papillonanes; on the arrangement of herburg, by Stg. L. Micheletti; and others of special interest to Italian Botanina, by Stg. L. Micheletti; and others of special interest to Italian Botanina.

SOCIETIES AND ACADEMIES.

Royal Society, April 16 — "An Attempt to determine the Adiabatic Relations of Ethyl Oxide Part I. Gazeous Ether." By Prof. W. Ramsay, F R S, and E. P. Perman, B Sc.
The object of the research described in the memoir is the

The object of the research described in the memoir is the determination of the behaviour of ether in the state of gas approaching towards the state of liquid, when heat is communicated to it, so as to alter its condition adiabatically.

cated to it, so as to after its condition adiabatically.

Previous researches by one of the authors in conjunction with

Pr. Sydney Young have yielded data regarding the relations of

pressure, temperature, and volume of gaseous and of liquid

pressure, temperature, and volume of gaseous and of liquid ether from which the values of the isobanic and of the noshore differentials are obtanable. Such results lead directly to a knowledge of the differences between the specific heast at contant pressure and those at constant volume; and these differences are not constant, but vary with varying volume, pressure, and temperature

The meroor contains an account of experiments made to determine the ratio between the peach bests at constant persons and those at constant volume. The velocity of sound an gescous either was determined at various temperatures, pressures, and volumes; and by means of the lockbermal differentials, and the experimental results for the velocity of sound, the ratio between the two specific heats were calculated. From the difference and the ratio of the specific heats, the values of the specific heats.

The geteral conclusion is that, for any constant volume, the specific heat, whether at contain volume or at contain pressure, decreases to a limiting value with rise of temperature, and subsequently increases; and that the change with temperature is more rapid, the smaller the volume

At large volumes, the specific heats tend towards independence of temperature and volume, while at small volumes the influence of change of temperature and volume is very great.

The authors are at present investigating similar relations for liquid ether,

Zoological Society, April 21 — Prof. W. H. Flower, C. B., F. S., Perdieden, in the char — & communication was read from Leat Colonel Str. Oliver B. C. St. John, R. May 1.—Suty-second Anniversary Meeting —Frof. Flower, F.R. S., President, in the chair—After the sudiors report had been read, and other preliminary business had been transacted, the been of the Council on the proceedings of the Society during report of the Council on the proceedings of the Society during 11 stated that the number of Fellows on January 1, 1891, was 124, being 4 less than the corresponding number in 1890 was 124, being 4 less than the corresponding Washers and the Corresponding Members had been elected to fill seasoness in those lists. In recognition of the effective protection accorded for sity years to the Great Stau, Sixtemarisms darrinafeaty) at two of in three British breeding stations—namely, in the Jaisad two of in three British breeding stations—namely, in the Jaisad with the Society of the Society and the same family, and in the Island of Foult by the late Dr. Socit, of Melby, and his son, Mr. Robert T. C. Socti—the Society And Society And

not quite cynal to thore of 1880, had exceeded those of 1886 by upwards of £1000, and might be deemed to be satisfactory. The wordinary expenditure for 1850 had been £123,48 of 1.14, which was £659 as £6 more than the corresponding amount for 1880, had were £123,48 of 1.14, which was £659 as £6 more than the corresponding amount for 1880, because the area removings argument of £259 to £15, 250. The balance brought up the total expenditure of the year to £25,572 tr. £6. The balance brought forward from 1880 was £1243 1; 114, and this, added to the motions received in 1890, give a total sum of this company of the continuery and the satisfactory of the total transport of the year to £25,72 tr. £6. The balance brought forward from 1880 was £1243 1; 114, and this, added to the motions received to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of the mortion of the total sum of £1000 to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of the total sum of £1000 to the reduction of the mortion of £1000 to the reduction of the reduction of £1000 to the reduction of the mortion of £1000 to the reduction of £1000 t tne work cone by British and foreign roologists during the year 1836, had been issued to the subscribers in December last, and had thus been published before the close of the year after that to which it relates. The library had been kept in good working order during the past year, and had been much frequented by order ourning the past year, and not occur much requestions, working goologists. A large number of accessions, both by gift and purchase, had been received and incorporated. In the Gardens to only new work carried out in 1890 had been the completion of the improvements of the Monkey House, but a large number of repairs and renewals of the different buildings in the Gardens had been made, and other minor improvements had been carried out. The number of visitors to the Gardens during the out The number of vintors to the Gardens during the year 1890 had been 64,0857, the corresp ording number in 1899 having been 644,597. The number of school children domitted free in 1890 was 13,935. The number of animals in the Society's collection on December 31 into was 255, of which offsy were mannial, 1273 birds, and 250 repeale Amongst the additions made during the past year, twelve were specially commented upon as of remarkable miners, and in most cast ergare mented upon as of remarkable interest, and in most cases repre-senting species set to the Society's collection of About 26 Gardens during the summer of 1890. The report concluded with a long list of the donors and their various donotions to the Menagerie during the past year—A vote of shakis to the Menagerie during the past year—A vote of shakis to the FR S, seconded by Mr A, I Socia, and carried unanimously —The report having been adopted, the meeting proceeded to circt the new Members of Connol and the onliners for the etect the new Members of Council and the others for the ensuing year. The usual ballot having been taken, it was announced that Mr. William T. Blanford, F. R. S., Dr. Albert Gunther, F. R. S., Mr. E. W. N. Holdaworth, Sir Albert K. Rollit, M. P., and Mr. Howard Saunders, had been elected into the Council in the place of the retiring members, and that Prof Flower, CB, FRS, had been re-elected President, Mr Charles Drummond, Treasurer, and Dr Philip Lutley Schater, FRS, Drummond, Treasurer, and Dr. Philip Lutley Solater, F. R.S., Secretary to the Soletiey for the ensuing year.—The remaining business having been concluded, the Fresident handed the silver medial of the Society to Mr. Thomas Edimondston, who attended to the part of Mr. Trans. Edimondston, of Dimest, and the part of Mr. Trans. Edimondston, of Dimest, the part of Mr. Trans. Edimondston, of Dimest, behalf of Mr. Robert T. C. Society of Melby, Shelland, in recognition of the effective protection accorded by them and their families repetitively to the Great Sizus as its breeding places in the Shelland in Section 1997. The proceedings terminated with the usual over of flushes to the Fresident.

Geological Society, April 22.—Dr. A. Gehle, F.R.S., Fresident, in the chart.—The following communications were read:—Results of an examination of the crystilline rocks of the General C. A. McMalion. The existion, in company with the Rev. E. Hill, spent a considerable part of last August in examing anew those sections in the Linard district which had proposed to the control of th

whose valuable contributions to the knowledge of the crystalline rocks of this district are well known. That the Lizard serpentines are altered peridotties may be regarded as settled, but doubts are ancrea periodities may be regarded as settled, but counts have been expressed as to their relation to other associated rocks, and as to the meaning of a streaky or banded structure exhibited by certain varieties. The authors, after re-examination of a large number of sections, feel no doubt of the accuracy of their original view that the peridolite was intruded into the hori-blende sobists and banded "granulitic" rocks, after these had blende schists and banded "granultic" rocks, after these had assumed their present condition. In it they find no signs of any marked pressure metamorphism, either prior or posterior to serpentinisation. They have failed to connect the streaky or banded structure with any foliation or possible pressure-structure. in the schists, and they can only explain it as a kind of fluxionstructure, viz as due to an imperfect blending of two magmas of slightly different chemical composition, anterior to the crystalliza-tion of the mass. The Porthalia sections have been examined with especial care, not only because the serpentine is nowhere so conspicuously handed, but also because its intrusive character has been denied, both it and the hornblende schists being ascribed to the alteration of a series of sedimentary rocks of suitable com-position. For this view the authors have failed to discover any evidence, and consider it contrary to stratigraphical and petro graphical facts. In regard to the genesis of the crystalline graphical facts. In regard to the genesis of the crystaltine schaus, which for purposes of reference were dwided by Prof. Bonney into a "ignatulitie," a "homblender," and a "intermediate of the professional profes sufficiently to allow of the two flowing for some little distance together, after which crystallization took place. In regard to the hornblende schots, the authors are not yet satisfied that either fluxion or mechanical crushing will account for every entiret motion or mechanical critisming will account for every production, the control of the co seice, the authors are doubtly whether it is any longer worth while separating it from the hornblende schuss. Of the igneous rocks newer than the serpentine, the gabbro has received the closest attention. It results in places (especially in the great dyke-like mass at Carrick Lur) a very remarkable foliation or even muneral banding, which has been claimed as a result of dynamo-metamorphism. The authors bring forward a number dynamo-metamorphism The authors bring forward a number of instances to establish the following conclusions:—(a) That this foliation occurs most markedly where the adjacent serpentine does not show the slightest sign of mechanical disturbance, rock, (c) that it sets in and out in a very irregular manner, (d) that when it was produced the rock was probably not a perfect fluid. Hence they explain it also as a kind of fluxion structure, produced by differential movements in a mass which consisted produced by differential movements in a mass which consisted of crystals of felaps and pyrosene, floating fluckly in a most or less viscous magna. The author's investigations tend to prove that (a) structure curvously similarity or distribution may be produced in fairly conselly crystalline rocks by fluxioned move-ments anterior to crystallization, and that (d) structures which of late years have been considered and the constraint of years more allies exclusively. This is productly the true evolution of a morphism subsequent to consolidation must have, in many cases, as like explanation. This is probably the true explanation of a large number of banded guesses which show no signs of crushing and holocytakiline, but in their more misuate structures differ from normal igneous rocks. The authors have seen onlying which has been favourable to the dead that pressure has artised the temperature of solid rocks sufficiently to soften them A discussion followed, in which Str. Teall, the Rev. E. Hill, Prof. Hull, the President, General McMahon, and Prof Bonney took part.—On a spherulitic and perlitic obsidian from Pllas, Jalisco, Meaco, by Frank Rutley.

Royal Microecopical Society, April 15.—Dr. R. Braith-waite, President, in the chair —Mr. T. Charters White presented three alides of sections of teeth permeated with collodion.—A letter from Mr. J. Aitkin, of Falkirk, was read, on a spot-mirror

method of illumination.—An abstract was read of a paper, by Surgeon V Gunson Thorpe, K.N., on some new and foreign Rottlera found on the West Coast of Africa, and belonging to the genera Trackesphere and Florusiaria.—Mr E. M. Neison exhibited two forms of bulli-eye condenser—one made like son exameters we obtained to business of the service consensarious was made like. Herechel's applianate, the other a new and simpler form, being made of two plane-convex lenses. This condenser seemed to asswer its purpose admirably, the amount of spherical aberration being only about one-fifth of that which existed in the old form—Mr. Nelson also reads some further notes on Distom structure. own also read some further notes on Diatom struc-tures as test-objects, which he illustrated by photographs— Mr C. Haughton Gill's additional note on the treatment of Diatoms was read, the subject being illustrated by photo-micro-graphs. Mr Mayall said the problem Mr Gill had endea-youred to solve was as to the existence or not of cellular structure in Diatoms estending through their substance, and he sought to demonstrate this by making chemical depositions which would probably fill up the cavities sufficiently to be distinguished by the microscope. Mr. Gill's observations were of great interest. because he had experimented with the definite ournose of testing because he had experimented with the definite purpose of westing a special point, thus applying to microscopy what Hershell would have termed an "experiment of inquiry"—a direct questioning of Nature on a point that had hitherto been regarded as almost beyond the sphere of experiment.

Academy of Sciences, April 27 – M. Ducharite in the character of Sciences, April 27 – M. PRACTICAL GEOLOGY.

Aids in Practical Geology By Grenville A J Cole, F.G.S., Professor of Geology in the Royal College of Science for Ireland. (London. C. Griffin and Co, 1891.)

An Introduction to the Study of Petrology the Igneous Rocks. By Frederick H Hatch, Ph.D., F.G S (London. Sonnenschein and Co., 1891)

OWEVER prophetic may have been the far-seeing premonitions of men in advance of their age in the dim past, and however invaluable may have been the additions made to the superstructure since, it can scarcely be doubted that the foundation-stones of geology were laid by Scotchmen and Englishmen towards the end of the last, and during the earlier part of the present century. And what a charm is there about the story of these sturdy pioneers, not perhaps quite the men whom one would have picked out as most fitted or most likely to become the fathers of a new science. It has about it the elements of a genuine romance. For the early training of few of these men was such as to give a scientific bent to their mind, they did not have what we are pleased to call "the advantage of a scientific education". it is probable that they never spoke, perhaps never dreamed of, such a phrase as "the scientific method," which we are so fond of formularizing, and on which we plume ourselves somewhat. But in spite of these seeming drawbacks, rather perhaps because with these men genius was allowed to run its spontaneous untrammelled course. they opened out to mankind a domain of knowledge the very outskirts of which had been barely touched upon before. Of shrewd mother-wit were they, too keen of eve to be wrong about their facts: not a few were ardent sportsmen, and the same instinct which led them to ride straight to hounds or patiently and warily to stalk the deer, led them also, as they brushed away minor details, to go direct to main issues, and carried them on, without rest but without haste, through the toils of many a year's steady field-work. With what awe and reverence do we look up to these giants when, we pass their achievements ın review I

Nor does it one whit impair this feeling of respectful admiration to turn to the other side, and cast a glance at what were their unavoidable shortcomings. They were too hard-headed to be illogical in the matter of straightforward inferences, but it was hardly to be expected that they would escape going astray sometimes when they ventured on recondite speculation. Rough is not the word for their method: incomplete would be nearer the mark, but even that can scarcely be applied when the means at their disposal are taken into account. No one had yet taught the value of the microscope and balance to the geologist: and, when these and other instruments of precision were introduced, there was just a tendency to gird at appliances that had a finnicking look about them to Titans who had so long and so successfully relied on their hammers and their wits.

But by degrees it became clear in Germany, and later on in England, that, though the great main roads of the

newly-discovered territory had been tracked out with such brilliant success, methods more refined than had sufficed for pioneering work must be introduced if all the intricacies of its lanes and by-ways were to be explored Then the swing of the pendulum rather tended to bring about a disposition to exalt the new means of investigation, and there was just a risk that the sound basis of field-work might come to be undervalued if not neglected; and that Mineralogy and Petrology, instead of being the handmaids of Geology, might be thought to constitute the whole of that science. But the mischief never went far. The mantle which had fallen from the shoulders of the great fathers was not to be lightly cast aside: and, while every new aid was cordially welcomed, the conviction grew stronger and stronger that honest work in the field must for ever be the starting-point of geological inquiry

How thoroughly this truth has become engiained in the minds of geologists is seen directly we open Prof Cole's "Auls in Practical Geology." A large part of the book is taken up with minute and precise directions for carrying out the vanous kinds of microscopical, optical, and chemical examination of minerals and rocks. But on the first page we read—

"Such aids in determinative geology as are given in the following pages may be applied in any halting-place, or in cities after the return from an expedition; but, in any case, observations made on specimens are of slight importance if uncoupled with knowledge of their true position in the field."

And again-

"After a study of a number of type specimens, the student is recommended to go out to some well described district, and to endeavour to recognize the varieties of igneous and sedimentary rocks by careful observation in the field. In this ways alone can he appreciate the various modes of weathering, the massive or minutes structures due to jointing, the smooth or rugged outlines that characterize the masses of which his hand-specimens form a part.

Nothing short of striking the rock-mass in the rock-mass in the postton and surroundings, even to the broader features of the landscape, should content the geologist who would follow worthly the founders and masters of the science."

Again and again the author resterates the lesson-

"Just as no mountain mass can be described by a stranger from a number of hand-specimens, however beautiful, so no rock can be adequately described from isolated microscopic sections Again and again the observer will pass from his section to the solid specimen, and from this, in memory at any rate, to the great mass of which it formed a part."

And in dealing with the nomenclature of igneous rocks, the chaotic state of which is so largely due to the ignoring of their field-relations, it is insisted that—

"The following out of an igneous rock in the field is a most important lesson, and will soon determine what is valuable and what is valueless in any proposed scheme of classification."

That the author, in these and similar passages, is not speaking from hearsay, not merely re-echoing what is now a trusm, is shown by the admirable practical directions which he gives in the first chapter for the outfit and procedure of the field-geologist. Here, and indeed throughout the book, the instructions are detailed and precise

The author has not forgotten the time when he was a beginner, his early failures, and the disappointments of his student-days, when, from the neglect of some slight precaution, he failed to obtain the results he had been led to expect; and he has used every means in his power, by minute and specific instruction, to shield those who use his book from similar mishaps. As an instance, take what he says about the effect of acids on minerals. How often has the self-taught man turned wearily to one book after another on mineralogy, in the hope of getting some definite information on this point, and all he arrived at was the curt statement, "Soluble in acids," which each apparently had copied from its predecessor, or all had borrowed from some common source. What acid? Concentrated or dilute? Cold or hot? Quickly, or perhaps only after a fortnight's boiling? points he was left to make out for himself as best he could The happier pupil of Prof. Cole is treated far more liberally, and will not have to weary himself by feeling about in the dark if he attend to the cautions and instructions of the book now before us. directions for blowpipe-work are equally precise Only one who has been himself an actual worker would have told the observer to wait "till the first red glow has gone off" before noting the colour of a borax-bead. Of course, anyone would, sooner or later, find this out for himself. but, till he had found it out, he would probably blunder not a little, and anything that economizes time nowadays is not to be despised. There is no need to multiply instances; everyone who uses the book will find that it eminently deserves the epithet of "practical," which the author has assigned to it.

But are there no weak points on which the critic may exercise his function? Attention may perhaps be called to the following .- On p 6, a graphical method, due to Mr Dalton, is given for determining the full dip of a bed from the dips on two oblique sections. The writer may perhaps be pardoned for preferring a method of his own, given first in the Geological Magazine for 1876, p. 377. But, independently of any personal predilection, it may be said that the diagram in the case of this method is simpler than in that of Mr Dalton. This makes it easier to recollect, and, besides, the fewer lines there are in a graphical construction the less is the chance of error. In dealing with " streak," it would be well to notice that the true streak of some hard minerals. Iron-glance for instance, is not obtained till they have been rubbed down in an agate mortar.

Doubt is thrown on the value of Turner's test for the detection of bonn (p. 4): there is an article by Dr. C. Le Neve Fouter in the Mineralogical Magazine (vol. 1: p. 77) which should be consulted in this connection. It is hardly worth while enticing the nomenclature and classification of the crystalline rocks. No two petrographers are magreement here, and probably the exusing schemes of arrangement are all of about equal value There is fortunately no multiplication of species or introduction of new names. It might be possible to take objection to the description of Quarti-felist as compact form of Grante, for the part played by the quarts in the typ occles is totally different, and must be correlated with a difference in their mode of consolidating. Quarti-felist sets are specially common as dykes, and there may have

been facilities for the escape of water in their case up the fissures which they fill, that were not present in the case of the more thoroughly buried magma of Granite It was doubtless the presence of water in the granitemagma which kent the quartz fluid or plastic after the other minerals had crystallized; its escape in the case of Quartz-felsite may have led to the early crystallization of the quartz. In dealing with the foliated rocks, the author touches on the debated point of the "true schists." We are pretty well used to this phrase, and have waited long in the hopes of being told what constitutes a "true schist. but our patience has not yet met with the reward it ments. The author is of opinion that "the alleged distinction between schist-like rocks and schists of pre-Cambrian age requires great delicacy of definition." This is delicately put, and will command the assent of most geologists

The paleontological section will perhaps be looked upon somewhat demayely by those well versed in biology upon somewhat demayely by those well versed in biology. But it will serve its end, which is to enable those who cannot pretend to any large amount of biological knowledge to know the commoner fossils when they see them, and determine the genus to which they belong. The method may have a large element of "rule-of-thumb" about it, it may be called empirical, but in a large number of cases it is not practicable to attain to anything better. And it has a certain educational value, for it makes a student use his eyes even if it but slightly disciplines his reason.

That the work deserves its title, that it is full of "aids" and in the highest degree "practical" will be the verdict of all who use it.

Nor will Dr Hatch's handy volume be any less welcome Those who wish to have in a compact form the prominent characters of the rock-forming minerals and the igneous rocks, will find all the information needed by a student concisely and lucidly put forth Some slight acquantance with crystallography and the optical properties of minerals is assumed. A short section on these subjects would have made the book more self-contained, and need not shave increased its size very materially

The igneous rocks are defined to be "those that have been formed by the consolidation of molten material." There is a spice of danger in the word "molten," for it may lead to the belief that the fluidity of the material was the result of "dry heat" in the case of a Laccolite the view so generally held is atken, that the overlying beds have been bent up by the intrusion of a molten mass. It is, to say the least, quite as likely that earth-movement caused a differential amount of bending in two adjoining beds, and that, as an empty space was thus gradually formed between the two, the molten matter was driven into it.

On the subject of the classification of the igneous rocks we find the following healthy expression of opinion.

"The various types are so mtimately related, that any attempt at rigid and systematic classification is not likely to meet with any great measure of success." Certainly not till some sounder basis of classification than any yet suggested is hit upon In the meantime Dr. Hatch's grouping is one that from its clearness and simplicity will be a real boon to the student.

A most useful feature in the book is the list of localities

where each rock occurs. The illustrations are very well executed. Though the book has appeared only recently, one teacher at least can already bear testimony, founded on actual experience, as to its value to students.

A. H. GREEN

BACTERIOLOGY.

Les Virus. Par Dr. S. Arloing (Paris: Ancienne Librairie, Germer, Baillière, et Cie., 1891)

THE name of Dr. S. Arloing as the author of a work on bacteriology is a sufficient guarantee that the book is worth reading, nor are we disappointed. "Les Virus" is one of the best volumes on this science yet produced. It is not a mere complation of other men's work, giving a categorical account of the numerous pathogenic and non-pathogenic bacteria now recognized,

Virus "is one of the best volumes on this science yet produced. It is not a mere complation of other men's work, giving a categorical account of the numerous pathogenic and non-pathogenic bacteria now recognized, but is a thorough scientific investigation into the principles of no of the most important branches of medical science, and might perhaps be better called a manual of "microbiology".

The work is divided into six parts, under the following heads .-

- (1) General considerations as to the nature of the bacterial poison
- (2) Form and mode of life of the microbes (biology)
 (3) The part taken by the microbes in the propagation
- and spread of infectious diseases.

 (4) Struggle of the host against the poison Natural
- extinction and artificial destruction of its effects
 (5) Immunity enjoyed by the body against certain
- microbes.

 (6) Attenuation and reproduction of the bacterial

It will be seen by the above list that this work covers a large field, and one not exactly dealt with by any previous author.

In the first part, which is subdivided into six chapters, Dr. Arloing commences with an historical survey of the science of bacteriology, pointing out the gradual extension of ideas from the time of Rhazes, who, in the ninth century, attributed small-pox to a process of fermentation "comparable to that which takes place in the juice of the grape when made into wine"; touching then on the works of Rayer, Davaine, Chaveau, and others, the author traces the development of the science until present times and the discoveries of Koch and Pasteur. An interesting comparison of the "virulent" parasites with simple parasites, such as Trichina spiralis, then follows; and, next, the formulation of two statements which form the basis of the modern science (1) the active agents of the virulent process are organisms; (2) these organisms are living, and possess specific properties.

The second part of the work deals with the biology of bacters. The methods of cultivating them are fully described, and, what we do not remember to have seen in any other work on bacteriology, there is a full account of the effect on micro-organisms of nourshment, temperature, light, atmospheric conditions, and electricity. In this part, also, are two most important chapters—namely, the effects on the microbes of the nature of the cultivating medium. This is only just beginning to be properly us-

derstood, and its investigation has already been productive of valuable results

The chapter on the products of the growth of microorganisms is hardly up to the general excellence of the work. It has not been sufficiently brought up to date, so that the researches of Dr. Hankin, and the more complete investigations of Dr. Sidney Martin in reference to the albiumnoses and alkaloids, do not appear in it. The disastess and promaines are, however, fully discussed, and much may be learnt from a previal of this chapter

The third division of the book is devoted to the ride which the microbes play in the propagation and causation of disease. The chapter on contagion is one of the best in the book, and would alone form a most valuable brockure. After a consideration of the general modes in which contagion is carried, a most exhaustive account is given of air, water, soil, food, and antificial inoculation (vaccination) as carriers of disease. As a natural sequence, the modes of entry of the germs into the body are then described, auto-infection being included, and next we have a consideration of what may become of the organisms after their entry, and the changes which take place in the host. The descriptions here given are exceedingly precise, and, although rather condensed, convey all that can be desired.

Passing now to the fourth part, we find four chapters devoted to the strife between the host and the microbes, and the natural extinction and artificial destruction of the posson. In the third chapter the subject of disnifiction is noticed, both by heat and antiseptics, special attention being drawn to the necessity of the careful disnification of sputum, linen, bedding, &c.,—points which cannot be too strongly insisted upon in all hospitals, and not merely in those devoted to fevers or diseases of the chest.

The fifth part deals with the very difficult, and, at present, vague subject of "immunity" Dr Arloing dimunity into two classes—"acquired" and "natural" On this subject no one is more qualified to speak than the author of this work, for he has made it almost a special study for years, and it is treated of in his usual masterly way.

The sixth and last part contains some of the more recent researches (especially those of Pasteur) on the attenuation of the virus.

Taking the work as a whole, we cannot speak too highly of it. We heartly congratulate the author on the success of his labours. The book is well illustrated, and we cordially recommend it to all those who wish to study a subject so replete with interest and of such vital importance to mankind.

Fil. W.

OUR BOOK SHELF.

Anleitung zur Bearbeitung meteorologischer Beobacktungen fur die Klimatologie. Von Dr. Hugo Meyer. (Berlin: Julius Springer, 1891)

WERR this little book less severely technical in form, it might be commended to the notice of that large class of observers whose sole aim and object in meteorological registration is to ascertain the characteristics of the local climate and to compare them in detail with those shown by the similar records of other places. It teaches how the results of observation may be tabulated or graphically

represented in the forms most approved by climatologists, and discusses with much precision the meaning of different kinds of mean values ; though, indeed, it omits all mention of the geometric mean, the application of which in climatology was lately under discussion in the Royal Meteorotology was lately under discussion in the Royal meterological Society. But it is, we fear, hardly elementary enough to meet the requirements of beginners and amateurs, especially such as regard a formula of any complexity with something of that distant respect that they accord to holy mysteries; and on the other hand it aims at nothing beyond the formal and statistical presentment of facts, and never deviates into the seductive, if sometimes illusive, field of physical causation. It is what its title proclaims it to be, a guide to the working out of meteorological observations for the purposes of climatology—the chimatology, that is to say, of the temperate cone. For those who work in a more extended field, some of the author's methods and dictates may be found to need modification. His schedule may be found to need modification. Its scneouse of the sual hours of observation makes no mention of those most frequently observed in the tropics, and his uncompromising condemnation of the use of Lambert's formulæ in reducing wind-registers, however justifiable in the case of the variable winds of these latitudes, ignores that of countries where tradewinds or monsoons blow steadily for weeks or months together with but little deviation from the normal quarter, together with but fittle deviation from the hormal quater, and where the direction undergoes a regular oscillation daily. In working out this daily oscillation at such places, the use of Lambert's formula is not only justified but almost indispensable.

Within the somewhat narrow limits that Dr. Meyer has prescribed to himself, he has executed his task carefully and conscientiously, but in this country, at least, his merits are likely to be appreciated by only a small class; chiefly, indeed, by that estimable few who find in plodding labour its own sufficient reward. The student wno is encoved with some snare or scientific imagina-tion, who loves to trace the inner workings of Nature, and sees in diagrams and tabulated statistics only means to this end, will find Dr. Meyer's work a somewhat dry study; and when he shall have mastered its contents, should he ever be challenged by Arthur Clough's "Questioning Spirit," and asked.

"What will avail the knowledge thou hast sought?"

he must answer as he best may from his own mental resources. His author, at least, will not help him to a reply.

Intensity Coils how made and how used. By "Dyer" Sixteenth Edition (London: Perken, Son, and Rayment)

In this book a simple and interesting account is given of galvanic batteries, induced electricity, and the methods of making and using intensity coils, which include numerous experiments that may be described briefly as "popular." In the present edition many other branches of the subject have been touched upon, including electric lighting, elec-tric bells, electric telegraph, electric motors; and a few words are said on the telephone, microphone, and phono-graph. Although the book is not presented as a scientific treatise, but simply as a guide containing the necessary instructions for making and using the above-named instruments, yet by its means many may be led to make a more advanced study of the subject, which to-day is of such high importance

General Physiology. By Camilo Calleja, M D. (London: Kegan Paul, Trench, Trubner and Co., Limited, 1890.) THE author of this book means by the word "physology "discourse of nature"; and his intention is to denote by it "the study of positive science in the abstract denote by it "the study of positive science in the abstract expressed the mission of allowing the subject to drop because senies." The scheme he has set before himself is solong [1] considered that the discussion had arrived at a stage what.

less than " to comprehend under the fundamental principle of mechanism—conservation of energy—all the laws and theories concerning nature." In order to show the spirit in which he sets about the accomplishment of his task, it may perhaps be enough to say that he regards the planets as "bodies constituted of organic and inorganic matter," and that to him living organic matter seems "the proximate agent of planetary movements, for which non-living bodies are only the cosmic medium."

The sun, we learn, is not "a body in combustion." but "principally a great reflecting mass, which, situated in the focus of the orbits of many planets, reflects their the rocus of the orbits of many planets, reflects their infra-luminous emissions, these producing light by their conglomeration." As for "natural light or daylight," it is "a photohermic radiation produced by transference, not only of the radiating motion of the planets, but also of the motion engendered by solar living beings." If anyone is attracted by writing of this kind, he will find plenty of it in Dr. Calleja's amusing volume.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Nisther can he undertake to return, or to correspond with the votiets of, especial manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

Co-adaptation.

It sometimes appears to me that the neo-Darwinians must speak a language of their own, because they are so fond of telling me, in a stereotyped phrase, that, "if words have any meaning," such and such words have expressed some meaning which no such and such words have expressed some meaning which no ordinary grammatical construction can extract. The present is a good case in point Prof Meldola says that he finds "a remarkable discrepancy" between my two previous letters on the above subject, and seeks to reveal it by quoting from the first letter, thus -

""I do not . . hold myself responsible for enunciating M Herbert Spencer's argument, which the quotation sets forth, merely reproduced it from him as an argument which appear to me valid on the side of "use-inheritance". For not only d hold myself responsible for enunciating Mr For not only did Darwin himself invoke the aid of such inheritance in regard to this identical case, . . '&c If words have any meaning, this identical case, . '&c If words have any meaning, this implies that Dr Romanes agrees with Darwin in regarding this case as one in which 'use-inheritance' played a part."

Does it? When a man says that in his opinion a certain argument in favour of a certain conclusion is valid, is this argument in favour of a certain conclusion is valid, is this equivalent to his asying that he accept the conclusion? And when he adds, lwice over, that he purposely abstains from expensing any opinion of his own with regard to the conclusion, is this equivalent to his saying the precise opposite? The tast of the case is unpily as follows. Mr. of Meddoin reproduced "it, "white the case is unpily as follows. Mr. Spencer's conclusion," I write to show that this particular argument was stayled. But the three was another argument.

reproduced Mr. Wallace's argument against Mr. Specier's deficience of "use-sinebraneae." I wrote to show that the partial deficience of "use-sinebraneae" involve to show that the partial control of the production of the state of the state

those who were interested in the matter would be able to form those who were interested in the matter would be able to form their own oplinon as to the value of the arguments adduced on either side of the question. I very much regret to find, how-ever, that Dr Romanes—whose amount of spare time appears to be most enviably inexhaustible—still_finds it necessary to prolong the correspondence. I am compelled, therefore, to enter the field once more, II only for the purpose of presenting my own case in its true light. What Dr. Romane's position may own case in its true light. What Dr. Romane's position may each of his contributions to the sulpet, that I am not the first who has lost has way in attempting to thread the masse of this writer's productions. As fer as I am concerned it will suffice to say that munication. In the review of Mr Pascoc's hook, from which this discussion originated, I did not merely reproduce: Wh. Wallace's argument against Mr. Spencer's idefence of "me inheritance." prolong the correspondence. I am compelled, therefore, to enter phasizing the importance of the factor of superimposed I pointed out that large numbers of cases of co-adaptation might be thus accounted for, and I used Mr Spencer's own illustration by way of example In summing up his own conclusion, parts by variation and natural selection appears to me, therefore, to be a wholly imaginary difficulty which has no place whatever in the operations of Nature" ("Darwinsm," p 418) Not only, therefore, has Dr Romanes misrepresented my view, but he has gone further. The other "argument on the same side" referred to in the above communication is this very denial of co-adaptation as a fact in Nature. This, with most amazing sanglested, is now claimed by my correspondent, who speaks of it as "the one which I had stated"! I must leave it to others to decide what value can be attached to the statements of a writer who adopts the principle of appropriating an argument, and pitting it forward in a manner which would lead most readers to consider that he had been the first to elaborate it simply because he has expressed the same idea in abstract ols instead of in concrete terms.

symnois instead of in concrete terms.

The next phase in the discussion is the admission by Dr Romanes that Mr Wallace's conclusion is correct, i.e. that co-adaptation is non-existent "As it appears to me, from his puly, that Prof Meldola's views on the subject of 'co-adaptation'. that Prof. Meddolfs view on the subject of 'co-adaptation', are really the same as my own, I rist once more in order to point out the deatity" (NATURE, vol. slin; p. 583) Mr. Romane did most, therefore, than imply point out that we were spread that this was "the only argument which could be were spread that this was "the only argument which could be a supported to the same of at any rate it appears to be intelligible among themselves, it and yellow the conveys their views with respect to the conveys the conveys their views with respect to the conveys the only from the circumstance that they have been enabled to

Physiological Selection and the Different Meanings given to the Term "Infertility.

In the discussion concerning the segregation of varieties occupying the same region, and the influence of physiological selection in securing this result, it is necessary that we consider selection in securing this result, it is necessary that we consider the different meanings given to some of the terms by different writers. The general fact on which Dr. Romanes insisted, in his paper on "Physiological Selection," was compatibility in the reproductive system of some, and incompatibility in that of others belonging to the same species On p 360 of his paper we read that "racial incompatibility," "however produced," "is the primary condition required for the development of varie-ties into species" Infertility and sterility are also used by him as ties into species — intertuity and sternity are also used by non-acquivalents for incompatibility in the reproductive system. Thus, on p 400 we find the statement that "All natural varieties which have not been otherwise prevented from Intercrossing, and which have been allowed to survive long enough to develop any differences worth mentioning, are now found to be protected from intercosing by the bar of sterlity—that is, by a previous change in the reproductive vystem of the kind which my theory

requires "

Dr Romanes did not attempt to catalogue the different forms of discriminative incompatibility that are included in the incompatibilities of the reproductive systems of different races, but reference was made to three forms (1) to compatibility in the reference was mane to ince forms (1) to compatibility in the time of flowering in those of the same race, as contrasted with incompatibility in those of different races, as on pp. 352 and 356, (2) to greater numerical fertility when the male and female elements of the same race unite, than when those of different elements of the same race unite, than when those of different mess unite, as in the note on p 354, and (3) to numerical in-fertulty through deficient production by hybrids, as on p 36, and p 357 in the note, and in the suggested experiments on an it the comparative "digrees of fertility" to be noted. To hote forms which were mentioned, we may add, as coming under the entergory of physiological incompatibilities, (4) lack of square in hybrids; (5) lack of adaptation in hybrids; (6) lack of excape from competition with kindred in hybrids; and (7) the vaperor energy and promptizes with which the male and female superior energy and promptness with which the make and temale clements until in pure unions, as contrasted with cross unions. Dr Romanes probably refers to this principle when he speaks of sternity as "failure to blend" (p. 565. It is last, when associated with the free distribution of the fertilizing clements, ensures the segregation (that is, the dis-

cruninative isolation) of two or more varieties occupying the eraminate robustion) of two or more varieties occupying the same area and propagating during the same season, and there-fore seems to me the most important of the forms of physio-logical segregation. This segregative principle, which I call potential or prepotential segregation, must, in almost every case, he operative between species and varieties that continue distinct while indiscriminately mingled on the same area and while fertilized by elements freely and indiscriminately distributed during the same season, for no other principle is able to secure during the same season, for no other principle is ance to secure free propagation and at the same time to prevent crossing under such conditions. Seasonal segregation is here excluded, and the other forms of physiological segregation when acting under such conditions are of little avail in preventing swamping unless curried to the extreme, and they then involve a waste of from one-half to the whole of the germs of the less numerous variety;

ofte-halt to the whole of the germs of the less numerous wartely; for the most favoursable case passible is when two vartetes occupy the area in equal numbers, and such cases rarely exit, expectally in the initial history of species.

Though aumerical infertility and tardy potency are readily distinguished, complete imposence and complete numerical sterility are more likely to be confyunded, for the complete incapacity of the unite and female elements of different varieties. for uniting involves failure to produce hybrids, as complete as or untime involves matter to produce ayonics, as computes when the elements untte without producing living offspring or germinating seed. The great difference is that in the case of cross impotence the geim remains unaffected by the alien fertilizing element, and therefore ready to be fertilized by any fertilizing element of its own kind that may reach it, while in the case of simple numerical cross sterility (if there be any such the case of sample numerical cross sterility it there be any such case; the shear elements promptly units, and therefore leave no case; the shear elements promptly units, and therefore leave no kindred fertilizing elements. Cross impotence, with prepotence of pure susons when associated with the free distribution of the fertilizing elements, produces positive segregation; for, when characterizing varieties occupying the same area, it canares the propagation of each with its own kind while preventing crossing; but suserned infectility of first crosses produces what I call but mannered infectility of first crosses produces what I call be provided to the produce of the produce of the produce of the preservation of datanct varieties the awapting effects of any crossing that takes place, and is therefore of great importance and the preservation of datanct varieties and species whose the post-four forms of hybrid inferiority mentioned above are also forms of negative eggregation, and, though of the highest importance when co-operating with prepotential aggregation or suprober principally of the preserving datanct varieties or species, when us-assisted by any degree of positive segregation.

We are sone prepared to see how the different meaning of facilities.

fertility have occasioned more or less misunderstanding in the discussion of physiological selection and its effects. Romanes, the seven forms of segregation above-mentioned are all forms of infertility between races, and therefore are all causes of commants, the seven forms of segregation stoyes-mentioned are all proposed and the companion of the companio

to limit the meaning of infertility between more to numerical in-entitility of first crosset, and then assumes that this is the only incompatibility that is included under physiological selection, and the property be attributed to this promotion. He effect that Before closing I wish to ruse the question whether a high degree of selective numerical fertility between races is not always associated with some degree of selective potential fer-titity. Or, using infertility in the more restricted meaning given tility. Or, using infertility in the more restricted meaning given in my nomendative, is not a high degree of segregate fecundity and cross infertility always associated with some degree of segregate two forms of loneomistibility are usually, if not always, associated in the segregation of species, is in not probable that they are smally associated in the segregation of varieties? Again, as we know that segregate prepotence, when associated with the free distribution of the fertilining elements, well produce prepotential segregation of the fertilining elements, well produce prepotential segregations. tion, effectually preventing crossing, without impairing powers of survival, and as there are many cases in which the continued survey, and as there are many cases in which the continued segregation of warieties occupying the same area is due entirely segregation of warieties occupying the same area is due entirely weakened forms of the principle associated with other forms of incompatibility in the reproductive system, and still other numerous cases in which partial isolation (produced by a slight diversily of habits, or by the occupation of adjoining distributions). would be speedily broken down except for these physiological incompatibilities, are we not fully warranted in the assertion that physiological selection is an essential factor in the evolution of many species?

to hypersonces. Security of the control of the form of segregation having been recognized, the question naturally arises as to what have been recognized, the question naturally arises as to what have been the causes through which the incompatibility has ceased to be entired on the ducussion of this point, I have given the uncertaintien to it. I think I have accorded in showing: (1) that any portion of a species subject to temporary isolation, through the compatibility of the property of the consistency of the compatibilities of the property owing to the constitution of reflex selection, by which the mutual fortuity and other compatibilities of an intergenerating stock are kept in force (see PATURE, vol. Am. pp. 26 and 569); (2) that partially incommittee the consistency of the property of the consistency of the consist ool., vol xxiii. pp 312-322). 26 Concession, Osaka, Japan.

Propulsion of Silk by Spiders.

Tropussion of SMR by Species.

The subnor ("O. P. C") of the stride on "Arachide", in the "Encyclopedia Britannica, "says the stride on "Arachide", the string of the species of the speci thinks, that (from microscopic anatomical investigations which thinks, that (from microscopic anatomical investigations would be has himself made) there is good evidence of spiders having the power to expel it; for he finds a certain muscular arrangement which would apparently suffice to give this power, and observers have actually seen the lines propelled."

Owing to the doubt herein expressed, may I ask your inser-tion of a chance observation lately made by me upon a splder, which has convinced me of the truth of the theory that spiders

tion or a chance observation lately made by me upon a splicin, which has convinced me of the truth of the theory that splicing do expel their lines at will, and this, too, as secondary to one of the control of the co who both witnessed with me, and at the same instant of time, the sudden appearance of the new line.

the sudden appearance of the new line.

With each successive trial, I was able to substantiate and
improve my observation; at first the appearance of the line
seemed instantaneous, as to its whole length; next I was able
to detect its elongation of itself after about 2 feet of its length

to detect its elongation of itself after about 3 feet of 18s length was visible, then I could see at leaving the spinnerts, and finally, during the last moment of its travel, I could perceive very distinctly that it drew the spider algabily floward.

From these premises I can but infer that the vision contained by the silic-glands, which, at the ordinary slow rate of eminsion, turns to goussmer immediately upon its exposure to the air, when expelled as now, woolenly, remains vanced sufficiently

an, when expelled as now, volcenly, remains viscid sufficiently long to reach a certain distance.

These secondary threads, carried towards the colling by the diplot, were a sevent brought down again when the felt to the diplot of the diplo

was coose to ner all ine time, and indeed the only object appar-ently which was close enough, the only hit me the first lime, when perhaps she had heard my approach; thus may strengthen the remarks made by Mr. C. V. Boys in your number for November 13, 1800, where he says: ". sight, as we understand the term, in spate of their numerous eyes, seems to

Antipathy [?] of Birds for Colour

WITH regard to the destruction of the yellow crocus by the Sparrow, mentioned by your correspondent "M H. M" in NATURE, vol. xlin p 558, this bird appears to have a pre-dilection for yellow. In an article on "Birds' Nests and Nestdilection for yellow. In an article on "sires Nests and rest-building," in the Annual World, present number, an instance is given of sparrows using the flowers of the laburium for hier nest. Only lately 1 have been watching them picking out they ellow centres of the daisy, but in this case it roas for food, and I am inclined to believe that some portion of the crocas is also eaten. At this time of the year they are well known to be partial to buds and flowers of different kinds—for instance, the blossoms of the gooseberry bushes

Doubtless, the bright yellow colour attracts the attention of this now much censured bird, so omnivorous in his tastes and such a general scavenger, and therefore not wholly to be condemned. Clevedon, April 28.

The Destruction of Fish by Frost.

REFERRING to Prof. Bonney's letter in NATURE, vol xlin. P. 295, regarding the destruction of fish by frost, and in which he asks for information from more northern latitudes, I may say that during the water of 1885-86, at Cape Prince of Wales, Hadson's Stratt, when the thickness of ice in a small lake was being measured, live fish were often seen; and upon the last occasion, when the ice measured six feet and half an inch, several were thrown up with the water that, upon our cutting through, imwere throwney mediately overflowed. These fish were about an inch and a neumediately overflowed. These fish were about an inch and a were extremely lively. I may add that during the summer both feeder and outlet of the lake averaged about eight summer both feeder and outlet of the lake averaged about eight to the proof feet in its deepest part. The inches in depth and the lake nine feet in its deepest part ches in thickness, covered the lake F. F. PAYNE inches in thickness, covered the lake Meteorological Service of Canada, Toronto, April 16

The Plying to Pieces of a Whirling Ring

WITH reference to the recent discussion in your columns on the whirling of steel bands, the following results will be of

interest. A weldless steel flask, with spherical body 12 inches in diameter and 8 inch thick, constructed for use in a centrifugation of the spherical forms of the spherical forms of the spherical flash of velocity.

At 16,000 revolutions per minute the body of the flask had

NO. 1124, VOL. 447

bulged 2 inches in diameter, this is equivalent to an extension of 17 per cent. of the circumference, the peripheral speed being 840 feet per second, and the tension 31 5 tons per square inch.
The experiment was not continued, as it was considered sufficiently satisfactory, and the bulged flask is kept as a curiosity.

McGill University, Montreal.

HERTZ'S EXPERIMENTS!

I N the last article the principles upon which a rapidly vibrating electric oscillator should be constructed were considered, and how the sudden break-down of the arr gap enabled these rapid vibrations to be started. It is probable that this break-down occurs in a time smaller than the thousand millionth of a second How very rapid interatomic motions must be !

Consider now the principles on which an apparatus is to be constructed to receive the vibrations produced by this oscillator. We may observe in the first place that as we are dealing with a succession of impulses at equal intervals of time we can utilize resonance to accumulate the effect of a single impulse Resonance is used in an immense variety of circumstances to accumulate the effect of a series of impulses, and is avoided in another immense variety of circumstances to prevent accumulating sounds, to keep clocks and watches going, to work telegraphs By avoiding it carriages drive safely over rough roads, ships navigate the seas, the tides do not now overwhelm the land, the earth and planets preserve their courses round the sun, and the solar system is saved from destruction Resonance may be thus described ~ If a system is able to vibrate by itself in any way, and if we give it a series of impulses, each tending to increase the vibration, the effect will be cumulative, and the vibration will increase. To do this the impulses must be well timed, at intervals the same as the period of vibration of the system itself. Otherwise some of the impulses will tend to stop the vibration, and only some to increase it. and on the whole the effect will be small. In order to use resonance in the construction of the detector of waves of electric force, we must make our detector so as to be capable of an electric vibration of the same period as the generator of the waves If we do this we may expect the currents produced in it to be increased by each wave, and thus the electrification at its ends to increase, and so increase the chance of our being able to produce a visible spark. Two ways of using a detector have been mentioned. One is to observe the heating of a conductor by the current in it, and the other to observe a spark due to the electrification at the end of the conductor. The latter is the most sensitive and has been most frequently employed, and is the method first employed by Hertz Two forms of detector may be used for observing sparks One form consists of a single conductor bent into a circle with its two extremities very close together. An electric charge can oscillate from one end of this to the other round the circle and back again. If the circle be the proper size, about 70 cm. in diameter for the large sized oscillator and about 5 cm. in diameter for the smaller sized one described in the last article, the period of oscillation of this charge will be the same as that of the charge on the generator of the waves, and its oscillation will be increased by resonance until, if the each of the circular wire be close by resonance until, it the ends of the circular wire be close enough together, the opposite electrification of the ends will become great enough to cause a spark across the gap. The other form of detector depends on using two conductors, each of which has the same period of electric oscillation as the oscillations we wish to detect.

Continued from p. 14.

are placed in such a position that an end of one is near are piaced in such a position that an end of our is are that end of the other which will at any time be oppositely electrified. For example, if the electric force in our waves be in vertical lines, then if we place two elongated conductors, one vertically above the other and separated by a very small air space, the electric force alternating up and down will cause currents to run up and down the conductors simultaneously, and the upper ends of both will be similarly electrified at any instant, while the lower end of the upper one will always be oppositely electrified to the upper end of the lower conductor, and if these two points, or two short wires connected with them, be close enough together, a spark will pass from one to the other whenever the electric force sets up these electric oscillations in the conductor. Thus this apparatus is a detector of the electric force. Whenever there is a spark we may be sure that there is electric force, and whenever we cannot get a spark we may be sure that there is either no electric force or anyway too little to produce sparks.

The apparatus will be more sensitive for electric forces. that oscillate at the same rate as the natural vibration of the electric charge on the conductor, because the effect of each impulse will then add to that of the last; resonance will help to make the electrifications great, and so there will be a better chance of our being able to produce a spark. We may weaken the strength of this air gap by reducing the pressure of the air in it. To do this the ends of the conductors, or wiles connected with them, must lead into an exhausted air vessel, such as a Geissler's There is no doubt that much longer sparks may thus be produced, but they are so dim and diffused that when dealing with very minute quantities of electricity those sparks in a vacuum are not more easily seen than the smaller and intenser sparks in air at atmospheric The additional complication and difficulty of manipulation from having the terminals in a vacuum are not compensated for by any advantages. This whole detecting apparatus works on somewhat the same principle as a resonator of definite size connected with one's ear when used to detect a feeble note of the same pitch as the resonator Such a resonator might very well be used to find out where this note existed and where it did not. It would detect where there were compressions and rarefactions of the air producing currents of air into and out of your ear. In the same way the conductor sparking tells where there are alternating electric forces making currents alternately up and down the conductor, and ultimately electrifying the end enough to make it spark. In the sound resonator there is nothing exactly like this last phenomenon. We have much more delicate ways of detecting the currents of air than by making them break anything. If anybody would allow the electric currents from a Herizian detector to be led directly into the retina of his eye, it would probably be a very delicate way of observing, though even in this direct application of the current to an organ of sense it is possible that these very rapidly alternating currents might fail to produce any sensible effect, for they are not rapid enough to pro-duce the photochemical effects by which we see.

To recapitulate the arrangements proposed in order to detect whether electric force is propagated with a finite velocity, and if possible to measure it if finite. It is proposed to create electric oscillations of very great rapidity, oscillating some four or five bundred million times per second, and it is expected thereby to produce waves of electric force whose length will be less than a metre of electric force whose length will be less than a metre if they are propagated with the velocity of light. It is proposed to do this by causing an electric charge to oscillate backwards and forwards between two con-ductors, and across an air gap between them. This oscillating charge is to be started by charging the conductors, one positively and the other negatively, until they discharge by a spark across this air gap By making the conductors small, and the distance the

charge has to go from one to the other small, the rate of oscillation of the charge can be made as great as we require If waves are produced by this arrange-ment, we can reflect them at the surface of a large conducting sheet, and then loops and nodes will be produced where the incident and reflected waves co-exist. The loops will be places where the alternating electric forces are great, while at the nodes there will be no electric forces at all In order to detect where there are these alternating electric forces and where there are none, it is proposed to use either a single wire bent nearly into a circle, with a very minute air gap between its ends, or else two conductors placed end to end, with a minute air gap between their ends In either case, if the natural period of vibration of a charge on the single conductor, or on each of the conductors in the second arrangement, is the same as the rate of alternation of the electric force we wish to detect, there may be sufficient electrification of the neighbouring ends to cause a spark across the minute air gap We are thus in possession of a complete apparatus for determining whether electric waves are produced, and what their wave-length is

The experiment is conducted as follows .-The two conductors which are to generate the waves are placed, say, one above the other, so that the electric are placed, say, one above the other, so that the electric charge will run up and down in a vertical line across the spark gap between them. They might be placed horizontally or in any other line, but for definiteness of description it is well to suppose some definite position. We may call them A and B. They are terminated in polished knobs, between which the spark passes. A and in are connected with the terminated of hardward and the spark passes. or a Wimshurst or other apparatus by which a succession of sparks may be conveniently made to pass from A to Before the spark passes, A and B are being electrified, and when the spark occurs the electricity on A rushes over to B, and part of it charges B, while the electricity on B rushes across the spark, and partly charges A, this taking place alternately up and down. Each time there is less electricity, for some is neutralized during each oscillation by the opposite charge; for energy is being spent, some in overcoming the resistance of the spark gap, i.e. in producing the heat developed there, and some in producing electric waves in the surrounding medium. Thus the electric energy of the two oppositely charged bodies A and B is gradually dissipated, and one way of describing this is to say that the two opposite electric charges combine and neutralize one another. This whole language of talking of electric charges on bodies, and electric currents from one to the other, of electric charges neutralizing one another, and so forth, is not in accordance with the most recent developments of not in accordance with the most recent developments or electro-magnetic theory. At the same time, those for whom these articles are written are familiar with this language, and with the rivew of the subject that it is framed to suit, while they are unfamiliar with effectively and electrically and magnetically strained and threeby the sext of electric and magnetic energy, and consequently it would have added very much to their difficulty in grasping the details of a complicated question if it had been described in unfamiliar terms, and from an unfamiliar point of view.

The electric force in the neighbourhood of the vertical generator will lie in vertical planes through it, and as A and B are alternately positive and negative, the electric force will alternately be from above downwards, and from below upwards. If, then, this force is propagated outwards in a series of waves, we may expect that all round our generator waves of electric force will be diverging; waves in which the force will be alternately down and up. The state of affairs might be roughly illustrated by elastic strings stretched out in every direction from our generator. If their ends at the generator be moved alternately down and up, waves will be propagated along the strings, waves of alternate motion down and up

In order to reflect these waves, we require a metallic sheet of considerable area some two or three wave-lengths away from the generator; so far away in order that we may have room for our detector to find the loops and nodes formed every half wave-length where the outgoing waves meet those reflected from the screen Not too far away, or our waves will be too feeble even at the loops to affect our detector. The waves are thrown off all round, but are most intense in the horizontal plane through the spark, so that our detector had better be placed as near to this plane as possible. The detector may be either a very nearly closed circle of wire, or two may be either a very nearly closed circle or wire, or two conductors, each somewhat longer and thinner than the combined lengths of the generating conductors, and placed vertically over one another, and separated by a minute air gap As the theory of this latter form of detector is simpler than that of the circle, it will simplify matters to consider it alone. The two conductors should each have a period of electrical oscillation up and down it, the same as that of the charges on the generator. The generator consists of two conductors certainly, but then during the time the spark lasts they are virtually one conductor, being connected by the snark across which the electric charges are rushing alternately up and down. Hence the period of oscillation of the charges on the generator corresponds to that on a single conductor of the same size as its two parts combined. Various exof the same size as is two parts combined. Various experiments have been made as to the best form for these conductors that form the detector. They might be made identical with the generator, only that the spark gap in the generator should be represented by a connecting wire They may be longer and thinner. If longer, they should be thinner, or they will not have the same period of manual of the whole, the best results have been got admiration. On the whole, the best results have been got with conductors somewhat longer and thinner than the generator. It is not generally convenient that the spark between the two conductors that form the detector should take place directly from one to the other It is not easy to make arrangements by which distance apart of these conductors can be regulated sufficiently accurately most convenient way is to connect the lower end of the upper conductor and the upper end of the lower one each with a short thin wire leading one to a fixed small knob, and the other to a very fine screw impinging on the knob. The screw may then be used to adjust the spark gap between it and the small knob with great acspark gap netween it and the small know with great ac-duracy. This spark gap must be very small indeed, if control to the spark gap must be well with the spark gap which is a spark gap. The minute sparks that are formed sparks gap when doing delicate work are too faint to the spark gap when doing delicate work are too faint to the spark gap when doing delicate work are too faint to the spark gap when doing delicate work are to faint to the spark gap when doing delicate work are to faint to the spark gap with the spark g Having placed the detector in position between the generator and the screen, the difficult part of the observation begins. It is heartrending work at first. A bright vation origins. It is neartrenuing work at Irist. Addignt spark now and then arouses hope, and long periods of darkness crush it again. The knobs of the generator require repoilshing; the spark gap of the detector gets closed up; dust destroys all working; and not without much patience can the art be attained of making sure of getting sparks whenever the conditions are favourable, or getting sparks whenever the conditions are favournote, though it is easy enough not to get sparks when the conditions are unfavourable. Before making any measurements, all this practice must be gone through. It is hard enough with the success of others before us to encourage us, with their advice to lead us, with a clear knowledge of what is to be expected to guide us. How much credit, then, is due to Hertz, who groped his way to these wonderful experiments from step to step, without the success of others to encourage him, without the advice of others to lead him, without any certainty as to what was to be expected to guide him. Patiently, carefully, through many by-paths, with constant watchulness, and checking every

advance by repeated and varied experiments, Hertz worked up to the grand simplicity of the fundamental experiment in electricity that is engaging our attention

Having gained command over the apparatus, we may look about for places where sparks occur easily, and for others where they cannot be produced Two or three places may be found where no snarks can be observed places inay be found where no spaces.

These places will be found to be nearly equidistant.

The distance in search of The distance They are the nodes we are in search of They are the nodes we are in search of The distance between any pair is half the distance an electric wave is propagated during the period of an oscillation. Their presence proves that the electric force is not propagated instantaneously, but takes time to get from place to place If the electric force were propagated instantaneously, there might be one place where the action of the currents induced in our reflecting sheet neutralized the direct action of our generator; but there could not be a series of two or more such places between the generator and the reflecting sheet. That there are more than one proves that electric force is propagated from place to place, and does not occur simultaneously everywhere. It sets the crowning stone on Maxwell's theory that electric force is crowning stone on Maxwell's theory that electric force is due to a medium. Without a medium there can be no propagation from place to place in time. It only remains to confirm by calculation that the rate of propagation is the same as that of light. This is a complicated matter in the same as that of light. This is a complicated matter in which is the question of how fast should, on the propagation is the same as that of light. theory, the charge oscillate up and down to the problem has only been accurately solved in a few special cases, such as that of a sphere by itself. conductors that have been employed are not this shape, are not by themselves, and so only rough approximations are possible as to the rate at which these oscillations occur. Knowing the wave-length will not determine the velocity of propagation unless we know the period of vibration , and consequently this direct measure of the velocity has only been roughly made, but it agrees as accurately as could be expected with Maxwell's theory that it must be the same as the velocity of light if electrical phenomena are due to the same medium as hight The conviction that more accurate determinations will confirm this agreement is founded upon safe ground It was pointed out that the ether that transmits light It was pointed out that the ether that transmits ingit and is set in vibration by the molecules of matter can hardly avoid moving them itself. This ether can hardly help having other properties than merely transmitting a comparatively small range of vibrations. It can hardly help producing other phenomena. When it has been shown that, if there is a medium concerned in constitution. veying electric and magnetic actions, it must possess properties which would enable it to transmit waves like light, and when it has been shown that there is a medium concerned in conveying electric and magnetic actions, and that the rate at which they are conveyed is approximately the same as the rate at which light is propagated, the conclusion is almost unavoidable that we are dealing with the same medium in both cases, and that future ex-periments, capable of accurate calculation and observation, will confirm the conclusion that electric force is tion, will confirm the conclusion that electric force is propagated through, and by means of, the luminiferous ether with the velocity of light. We really know very little about the nature of a wave of light. We know as great dead more about electric and magnetic forces, and much may be learnt as to the nature of a wave of light much may be learnt as to the nature of a wave of light much may be searnt as to the nature of a wave of sight by studying it under the form of a wave of electric force The waves produced by the Hertian generator may be a metra long or more. The difficulty is to get them short enough. We know a good deal about how they are pro-duced, and from this, and also by means of suitable de-duced, and from this, and also by means of suitable detectors, we can study a great deal about their structure.

They are truly very long waves of light. Atoms are
Hertzian generators whose period of vibration is hundreds of millions of millions per second. A Hertzian generator may vibrate rapidly, but it is miserably slow compared

with atoms. And yet the wonder is that atoms vibrate with atoms. And yet the wonder to the souls in so slowly. If a Herizian generator were, say, 10⁻⁷ cm. long, about the size of a good big atom, its period of vibration would be some hundreds of times too rapid to produce ordinary light. Atoms are probably complicated Hertzian generators. By making a comcomplicated afterizing generators. By making a com-plicated shape, as, for example, a Leyden jar, a small object may have a slow period of vibration. All that is required is that the capacity and self-induction may be large in comparison with the size of the con-ductor. We saw that these rapidly vibrating generators have but httle energy in them: they rapidly give out their energy to the ether near them. This is also the case with atoms. These, when free to radiate, give up their energy with wonderful rapidity. How short a time a flash of lightning lasts! It is hardly there but it is How short a time gone the heated air molecules have so suddenly radiated off their energy. The reason why atoms in the air, for instance, do not radiate away their energy like this is because all their neighbours are sending them waves Each molecule is a generator, but it is a detector as well. It is kept vibrating by its neighbours: it occupies a part of the ether that is in continual vibration, and so the atom itself vibrates. As each atom can radiate so rapidly, it must be a good detector : its own vibrations must be very much controlled by the neighbourhood it finds itself in; and as the waves of light are very long compared with the distances apart of molecules, those in any neigh-bourhood are probably, independently of their motions to and fro, each vibrating in the same way It is interesting to calculate how much of the energy in the air is in the form of vibrations of the ether between the molecules of air. A rough calculation shows that in air at the ordinary density and temperature only a minute fraction of the total energy in a cubic centimetre is in the ether; but when we deal with high temperatures, such as exist in lightning-flashes and near the sun, and with very small densities, there may be more energy in the ether than in the matter within each cubic centimetre All this shows how wide reaching are the results of Heriz's experiments. They teach us the nature of waves of light. We can learn much by considering how the waves are generated. Let us consider what goes on near the generator, consistcet us consider what goes on near the generacy consains of two conductors, A and B, sparking into one another. Before each spark, and while A and B are being comparatively slowly what is called charged with electricity, the ether around and between them is being strained. The lines of strain are the familiar tubes of electric force. If A be positive, these tubes diverge from all points of A, and most from the knob between it and B, and converge on B Where they are narrow, the ether is much strained; where wide, the ether is but little strained. Each tube must be looked upon as a tube of unit strain. The nature of the strain of the ether is of unit strain. The finance of the strain of the control of the original of the mature of the strain being unknown. We do not know the nature of the change in a piece of .rdia-rubber when it is strained, nor indeed in any solid, and though the ether is much sampler in structure than india-rubber, it can hardly be wondered at that we have not yet discovered its structure, for it is only within the present century that the existence of the ether was demonstrated while men have known solids and studied their properties and structure for thousands of years. Any way, there is no doubt that the ether is strained in these tubes of force when A and B are oppositely charged, and that the energy per cubic centimetre of unstrained ether is less than that of strained ether, and that the work done in man that of strained enter, and that the work done in what is called charging A and B is really done in strain-ing the ether all returned them. When the air gap breaky down, and an electric spark takes its place, there is quite a new series of phenomena produced. Suddenly, the strained ether relieves itself, and, in doing so, sets up new

motions in itself. The strained state was probably a peculiar state of motion, and in changing back to ordinary ether a new and quite distinct state of motion is set up. This new state of motion all round the conductors is most intense near the spark, and is usually described as an electric current in the conductors and across the spark, or as a rushing of the electric charge from one conductor to the other. The electric current is accompanied by magnetic force in circles round it, and the tubes of magnetic force define the nature of the new movement of simplicity, the existence of this magnetic force has been unnoticed It is due to a peculiar motion in the ether all round what are called electric currents. The current in fact consists of little else than a line, all round which this movement is going on; like the movement surrounding an electrified body, but also unlike it. Whenever electric forces are changing, or electrical bodies moving, or electric currents running, there this other peculiar motion exists. We have every reason for thinking that this, which may be called the magnetic strain in the ether, as the movement all round electrified bodies the ether, as the invenient all round electric strain only exists in these three cases. (1) when the electric strain only exists in these three cases. (1) when the electric surain is changing, (2) when electric currents are running. These three may be all cases of one action Certainly the magnetic strain that accompanies each is the same, and it seems most likely that the electric change is only another aspect of the magnetic strain. There are analogies to this in the motion of matter that partly help and partly annoy, because they partly agree and partly will not agree with the etherial phenomena. Take the case described in a former article of a chain transmitting waves. Attention was drawn to the displacement of a link and to its rotation. Now for the analogy: to seem at all satisfactory the first thing that would strike one would be to pay attention to two motions, to the velocity of displacement of the link and to its rotation. This would lead to interminable difficulties in carrying out the analogy. We cannot liken electric strain to a velocity in this direct and simple way, because, what are we to do with a change in the strain which produces the same effects as a continuous current? A change in the strain is all very well, it would be like a change in the velocity, but what about a continuous change in the velocity; we can hardly suppose a velocity continually increasing for ever we are evidently landed in immediate difficulties. It is better therefore to be content to liken the electric strain to a displacement of the chain link. It seems most likely that it really is a peculiar motion in the ether, but we must be content for the present with the analogy. If we want to drive it further, we must suppose stress in the chain that draws the link back to be due to a motion in the chain or of things fastened to it, and then the changed motions protungs rastened to it, and then the changed motions produced by a displacement of the chain might be analogous to the peculiar motions accompanying electric strain. It would lead us too far to work out this analogy. Returning to the simpler case of the displacement of the link representing electric strain, and the velocity of its rotation representing magnetic strain, see how the actions near a Hertrian generator may be likened to what takes place Hertisan generator may be likened to what takes place when a wave is being sent along a chain. While the conductors are being slowly charged we must suppose becture strain to be produced in all the surrounding space. This is a comparatively slow action, and as the rate of propagation is very rapid, the electric strain will rise. practically simultaneously in the whole neighbourhood, and that it does so is a niost important fact to be taken account of in all our deductions from these experiments.

This slow charging must be represented by a slow raising of one end of the chain, which raises the rest of it to a great distance apparently simultaneously if the raising be done slowly. Suddenly the air gap breaks. This might

be represented by lifting the chain with a weak thread, and by having the end of the chain fastened to a pretty strong spring. When the thread broke the spring strong spring. When the thread broke the spring would pull the chain back quickly, would pass its position of equilibrium, and thus commence a series of rapid vibrations on each side of this position the vibrations would gradually die away owing to the energy of the spring being gradually spent, partly on friction in itself, and partly in sending waves along the chain. In actually performing the experiment, an india-rubber tube or limp thin rope is better than a chain when hung horizontally, as the chain is so heavy; when it can be hung vertically, a chain does very well. In the description it simplifies matters to describe a chain, because it is easier to talk of a link than of a bit of the rope, a link has an individuality that identifies it, while a bit of the rope is so indefinite that it is not so easy to keep in mind any particular bit Consider now what keep in mind any particular bit Consider now what these waves are, what sort of motion originates them When the spring first starts, the near parts of the chain move first. What happens to any link? One end of it moves down before the other. What sort of motion, then, has the link? I must be rotating. Thus it is that change in the displacement is generally accompanied by rotation of the links Thus it is that change in electric strain is accompanied by magnetic strain. The analogy goes farther than this. Each wave thrown off may be goes farther than this. Each wave thrown off may be described as a wave of displaced or as a wave of rotating links, and the most displaced are at any time the most rapidly rotating links. Just in the same way, what have hitherto been called waves of electric force may also be looked upon as waves of magnetic force Because there are two aspects in which the motion of the chain may be viewed does not diminish from the essential unity of character of the wave-motion in its waves, and similarly the fact that these Hertzian waves have an electric and a magnetic aspect does not diminish from the essential unity of character of the wave-motion in them. At the same time the two elements, the displacement of a link and the rotation of a link, are quite distinct things; either might exist without the other, it is only in wave propagation that they essentially co-exist. In the same way electric strain and magnetic strain are quite different things; though in wave-motion, and indeed whenever energy is transmitted from one place to another by means of the ether, they essentially co-exist.

FIVE YEARS' PULSE CURVES.

OVER five years ago it occurred to me that there would be considerable interest in keeping a systematic record for some time of the rate of pulsation, ret of the number of beast (per minute) of the pulse. I therefore commenced the practice by taking, every night, an observation of my own pulse; these observations, originally undertaken solely for my own personal interest, have been considered to the consideration of the present considerable to the considerable of the five present country to the considerable of the five years, that I thought it might be interesting to readers of NATURE to have these results put before them.

First, then, as to the method adopted in these observavations. I count the pulse bears for one minute 'avery night' before returns to bed, and invariably while in a standing posture. From the records thus obtained the average for each month is deduced in the usual way, vizby adding together all the numbers for the month, and dividing by the number of days on which observations were taken. With regard to this important consideration

Thus avoiding the considerable error that is introduced by counting for, say. Afteen seconds only, and multiplying.

The time has wated from s 3 o clock to z o'clock

NO. 1124, VOL. 44]

is of the number of observations, since an insufficiency thereof would, of course, greatly vitiate the value of my curves—I may state that during the first four years I omitted to take an observation on only seventeen nights altogether. During the fifth year, I find twenty-one ob-servations missed. Nevertheless, the net data from which the curves are deduced are not quite so abundant which the curves are deduced are not quite so adminished his statement would imply; for, in calculating the monthly average, I have invariably struck out altogether all readings above 79. My reason for this procedure was simply that I wished to obtain a curve showing the normal pulsations; now, anything much above 75 is abnormally high (especially in my own individual instance, for it will be noticed that my pulse is below the usual average of 70), and I can nearly always assign a distinct cause, such as the feverishness caused by a cold, or excitement, or recent exercise; it therefore appeared to me fairest to knock out altogether the results of such disturbing causes, and since for this purpose an arbitrary line must be drawn somewhere, I decided to draw it at 79. On the other hand, bowever, I have retained all the 79. On the other nand, nowever, I have retained an tare other readings, no matter how low they might be, although the "fifties" are very common, and occasionally even the "forties" have been touched. It might, perhap, be thought that these very low readings should be neglected equally with the very high, but such a course appeared to me altogether illegimate, both because such low readings. seemed, judging from their occurrence, to be, so to speak, normally caused, and unassignable to any distinct extra-ordinary cause known to myself, and also because I should hardly have known where to draw a minimum line However, I now regret that the readings below 50, at any rate, were not rejected; but such readings are so extremely rare that they cannot have much influenced the curves. In order that the reader may judge for himself on what data these curves are founded, I have appended a table showing the net number of readings from which each monthly average was drawn, and have also stated (in brackets) the number of readings below 60 included in each month.

On the control of the

On examining the monthly curse, it is at once obvious that there is a strong similarity between the five years, clearly every year the curve falls through the spring, until about mediumner, and then rises wonderfully steadily assembly a strong the strong of the strong

(except that of the winter irregularity, 1889-90), I could assign a fairly plausible explanation. For instance, during the summer of 1886 I was under medical treatduring the summer of 1800 I was under incurcal treat-ment in July of 1800 I was touring among the Swiss mountains: while at the end of February 1887 I had removed from a low-lying northern suburb, to a rather higher southern one; this change might with some

pausishity be considered as the possible disturbing cause in the 1898 paring circus. Nevertheless, looking at the results as a whole, I was not satisfied with the curves: it appeared to me as by no means improbable that the monthly average was calculated on a rather too short perrod, thus allowing temporary disturbing causes to manifest themselves unduly, it therefore determined to try the effect of advantages. therefore determined to try the effect of calculating the averages on a two-monthly period, throwing into one total January and February, March and April, May and June, July and August, September and October, November and December respectively. On drawing the curves corresponding to these averages (thick-lined curve), I was delighted to find order and symmetry completely regnant : all the aberrations have of course disappeared, and order is supreme. This two-monthly curve clearly shows a single maximum in winter, followed by a fall to the minimum at midsummer, and then by a rise to the winter maximum

It is evident that the curves for all five years are very closely similar, though by no means identical in nature, but I am especially anxious to point out the extraordinary symmetry displayed by the curves on either side of a maximum or minimum point. For instance, the curves for the following periods,

1886 July-October, ,, April-December, ,, November-February 1887, 1888 November-May 1889, 1889 The whole year,

are wonderfully symmetrical, in some cases even being almost geometrically exact

What, however, may be the exact interpretation of these curves I must leave it to those better acquainted than myself with physiology to decide; but it is worth noting that these curves are exactly contrary to the statement in Michael Foster's text-book, that the pulse

is said to rise in summer 3 The following is the table above referred to as showing the net data for each month, and also (in brackets) the number of readings below 60 included in each case :-

1886.	1 1888.
January 28	January 25 (1)
February 19	February 23 (1)
March 21	March 24 (3)
April 25	April 30 (4)
May 30 (1)	May 30 (11)
June 29	June 30 (11)
July 30 (1)	July 31 (10)
August 28 (8)	August 28 (9)
September 20 (2)	September 28 (5)
October 29 (1)	October 31 (5)
November 25	November 26 (2)
December 23	December 28 (3)
1887	1889
January 28 (2)	January 25
February 26 (1)	February 23 (2)
March 30 (3)	March 31 (9)
April 27 (4)	April 28 (8)
May 27 (3)	May 28 (3)
June 25 (5)	
July 31 (3)	July 28 (4)
July 31 (3) August 30 (6)	August 28 (7)
September 28 (2)	September 27 (A)
October 30 (2)	October 30 (2)
November 23	November 26 (4)
December 25 (2)	December 25 (1)

		890.
lanuary	27 (5))	July 24 (2)
February	24 (5)	August 30 (8)
March	28 (4)	September 29 (7)
April	28 (7)	September 29 (7) October 24 (5)
May	27 (7) . 26 (8)	November 22 (I)
Tune	26 (8)	December 30

If these numbers be compared with the curves, it will be found that in a rough way they agree with them; the diminishing number of these low readings every autumn. no less than their increase towards the summer, being obviously correlated with the rise and fall of the curves. F. H. PERRY COSTE.

THE SCIENCE MUSEUM AND GALLERY OF

VIGOROUS protests continue to be made against the appropriation, for the new Gallery of British Art, of the site which ought to be used, as originally intended, for the Science Museum. Several letters on the subject by men of high authority have been printed in the Times, and on Tuesday a deputation, which could not but command attention and respect, waited upon Lord Cranbrook and Mr Goschen to represent to them the opinions held by all who are in a position to form a trustworthy judg-ment on the question The Government are still en-gaged in considering the matter, and it is to be hoped that they are receiving and giving heed to the counsel of their natural advisers, although, unfortunately, this is a priori extremely doubtful

We print the letters addressed to the Times by Sir F Bramwell, Mr. Poynter, and Sir J Coode, and an account of the proceedings of the deputation on Tuesday

It has for many years been recognized that the science collections at South Kensington are housed in a manner which largely diminishes their value for their principal use—viz. that in connection with the Royal Normal School of Science

This school, as every one knows, is, as regards its main building, situated on the east side of Exhibition Road, while the West Gallery adjacent to Queen's Gate

West Gallery adjacent to Queen's Gate
1a 1885 the Government appointed an inter-departmental
committee to consider the subject and to report, and they
charman of the committee. The committee fively not elssentienty reported in the sense that so the land lying west of
Exhibition Road, and between that road and Queen's Gate, suitable buildings should be certed according to a complete design,
but that they should be carried out in successive portions.

Nothing was done on this report.

In 1889 another committee was appointed; this committee made very similar recommendations, and last year the Govern-

ment acquired further land.

There are now on the west side of Exhibition Road, and immediately opposite the science schools, the observatories used by Mr. Norman Lockeer, and also a newly-creeted physical

aboratory.

Everything seemed to be, after all these years of walting, in train for affording the needed accommodation, when, incredible as it must appear, the Chancellor of the Exchequer announced that the whole of this well-considered and satisfactory strangethat the whole of this well-considered and satusfactory arrange-ment is to be given up. He stated it had been determined to sweep away the observationes and the physical laboratory, as the state of the state of the state of the state of the schools, and to devote the particular plot of ground to a picture gallery. I look upon this as a most disastrous proceeding, and one that, in the interest of the great National Department at the state of the state of the state of the state of the Asy one who will take the panes to wint the ground, or even to look at an accurate plan of it, will see that there is plenty of good space available for the picture gallery without interfering the state of the publisher at where proposed is no thoroughly prescuence as that,

with the needs or the science collection, and that the notion of building it where proposed is so thoroughly preposterous that, as our American friends say, it must have originated in "pure cuseofness." FREDERICK BRAMWELL. No. 5 Great George Street, Westminister, May 9.

NO. 1124, VOL. 44]

SIR FREDERICK IDAMWALL in his letter of this morning points out the disastrous effect on the interests of the national from the intrastance of the result of the national from the intrastance of the saw Callery of Britath Art, to be planted precisely on the spot where it will cause the greatest amount of incoordenience. To an artist a still more flagrant matance of "pure cussedness" in this matter would appear to be that the building should be placed where it can have no commeetion with the existing galleries, when there is a piece of ground higher up the road in immediate connection with them

The galleries on the east and west of the Horticultural

ground againer upon etc. on in minematic coloration with melin Grardena, which were built for pictures at the time when there was a scheme for bioding annual international exhibitions, are whether by a happy "falled" or by careful calculation on the part of their constructor, General Scott, without doubt the best of their constructor, General Scott, without doubt the best of their constructor, General Scott, without doubt the best seer been constructed in Baginal SS in Frederick Lengthon has, I know, expressed this opinion, and every artist who exhibited in these galleres during the three or four years that the skilled in the search of th

Why these huidings, acknowledged to be as good as they can
be, and actually ready on the spot, should not be used for this
presently according to the control of the spot of the spot
presently according to the spot of the spot of the spot
presently according to the spot of the spot
presently according to the spot now housed, thus affording provision for the extension of the collection, which is growing annually by the addition of the pictures purchased under the Chantrey bequest, and to which pictures purchased under the Chantrey occuest, and to which it is certain that further considerable additions will constantly be made by gift and bequest as yoon as there is a place in which they can be properly and permanently exhibited Also, there is for once, if advantage be taken of it, an oppor-

tunity for carrying out a reasonable and consistent scheme for both science and art. EDWARD I POYNTLE, R A

28 Albert Gate, S W , May 11.

HAVING served on the Committee on Machinery and Inven-tions in connection with the Science and Art Department of the Committee of Council on Education, I desire most emphatically to endorse the protest of Sir Frederick Bramwell which appears in your columns of this day's date.

Although the fees received from patentees up to the end of

1885 exceeded the expenditure of the Patent Office by upwards of 2 millions sterling, nothing practically has been done to put the Patent Museum and Museum of Machinery and Inventions

in an efficient condition.

ear after year the Committee, of which I am a member, has Year alter year the Committee, of which I am a member, has urged that more space should be given to the authorities at South Kenangton, and now, when it was thought the recommendations were about to be realized, it is asserted that the promued site is to the givent of the proposed of the proposed of the to the givent of the proposed of the proposed of I takerely trust that this intension may not be carried out, but that the site in question, which exactly faces the Royal College of Science, will be appropriated for the science collections, to

of Science, will be appropriate which purpose it has long been assigned JNO, COODE, President

The Institution of Civil Engineers, 25 Great George Street,
Westminster, May 11.

The deputation which waited upon Lord Cranbrook, the Lord President of the Council, and Mr Goschen was large and representative Mr. Plunket, Mr., First Commissioner of Works, was also present Among the deputation were: Sir William Thomson (President of the deputation were is it william I admissin (President of the Royal Society), Sir Berhard Samuelson, M.P., Sir George Gabriel Stokes (Past President of the Royal Society), Mr. C. Acland, M.P., Sir Frederick Bramwell, F.R.Se Breef, Story-Maskelyne, M.P., Sir Douglas Galton, C.B., Mr. Poynter, R.A., Prof. Unwin, Mr. Francis Galton, Prof. Ayrton, Prof. Flower, C B., Prof. Armstrong (Secretary of the Chemical Society), and Mr. Fletcher and Mr. Woodward, of the British Museum.

Prof. Story-Maskelyne, in introducing the deputation, in the absence of Sir Henry Roscoe (who is laid up with influenza), said it embraced a body of gentlemen distinguished not so much said it swhraced a hody of gentlemen distinguished not so midd by their numbers as by their character, representing as they did the Royal Society and the scientific mean of England. They by their numbers as they can be sufficiently as the scientific mean of England. They was the scientific mean of England. They who were deeply concerned in what he might call the new University which had mean for science at South Kensiquon foll the place now society of the scientific mean would have to go across the road to get to sanother and interesting branch of the National Science Collection and interesting branch of the National Science Collection and interesting branch of the National Science Collection of the Science of the Science Collection of believed that the Government would have to sak Parliament to supplement the grant of ASO, coo given by the anonymose donor. What he asked was that they should not be told off-hand that the scheme could not be elizered, but that they should be allowed to take the sense of Parliament as to whether the site was to be occupied in the way proposed or not. They objected to the money being simply asked from Parliament and the control taken out of its hands.

The Chancellor of the Exchequer —You may entirely exclude at. That will not be done. We shall take such precautions that. That will not be done. We shall take such precautions by trustees and by contracts that such a contingency will not

occur.

Prof. Story-Maskelyne said has was very glid to hear that. Sir William Thousson, on behalf of the Royal Society, and Sir William Thousson, on behalf of the Royal Society, and the second state of the Royal Society, and the second seco galleries in the world

gaueries in the world

The Chancellor of the Exchequer—Can you tell us—for I
have not yet been able to make it out—in what way the proposed arrangement would be fatal to the work of the College of
Science?

Sir William Thomson .- By cutting the school in two-by separating the school from the place in which the instruments

are kept.

The Chancellor of the Exchequer.—You mean that it is too

far to walk? Sir William Thomson,-It would be dreadfully risky to have

Sir whilm I norson.—It would be dreadnilly risky to have corry about delicate instruments.

Sir Bernhard Samuelson, as a member of a departmental committee which considered the question of housing the College of Science, supported Sir William Thomson's views, and pointed at that already there had been as necroachment upon the land which had been acquired for the purposes of the Science Museum

Moseum.
The Chancellor of the Exchequer.—It was purchased for The Chancellor of the Exchequer.—It was purchased for the Chancellor of the Mose of the chancelor of the Exchequer, after the assumance which he Chancellor of the Exchequer, after the assumance which he Chancellor of the Exchequer, after the assumance which he chancelor of the Exchequer, after the assumance which he man that, if there should be an expansion of the est gallery, owner one would be ready to extend the manifemence of the present donor.

present donor.

The Chancellor of the Exchequer.—I think that that is rather a matter for our grandchildren. I think there is plenty of space to fill with worthy pictures for a very long time to come.

Prof. Story-Maskelyne.—But £80,000 will not do it.

NO. 1124, VOL. 447

Sir B. Samuelson said he hoped the question of the site would Sit B. Samuelson said he hoped the question of the site would be reconsidered, and that those representing science should have the assurance that ample space would be given them not only for their present requirements but also for the extension which appeared to be looming in the future. The Chancellor of the Exchequer.—I am anxious to provide well for science. We hope to bring science into one centre fronting the Impernal Institute.

fronting the Imperial Institute, Sir B. Samuelono said that if they were given an area equal to the amount purchased last year for the purpose of science alone they only, in his opinion, to be content. But already alone they only in the purchase of the second would lead to having no actual claim to the ground would lead to further retroachment, which would, in the end, make it impossible for science to be efficiently provided for. The Chancellor of the Exchequer,—I am nazious to show you that, quite irrespective of my interposition, we have not been than the contraction of the contraction of the contraction of the Name of a safety section of the first and the same of the future

been to satisfy science in the most ample manner for the future

been to satisfy science in the most ample manner for the interest. Sir B. Samuelson said the art gallery was looked upon with a great deal of jealousy, and in the next place they feared that the full area of 200,000 feet, which they considered to be absolutely

run area or 200,000 test, which they considered to be absolutely necessary for the future requirements of science, would be encroached upon Sir Frederick Bramwell, who was chairman of the department all committee which considered the question in 1888, suid there was a sate to the north of the City and Guidé Institute, and from the east to the west there were galleries, and a cross gallery was being made by the Imperial Institute which would give com-munication one with the other, and which would be in immediate connection with the site he suggested. That would be an admirable art gallery He would be glad to see the Science School able art gallery He would be glad to see the Science School and everything belonging to it moved so that there might not be a road dividing it. He trusted that the anonymous donor might be induced to see that his gift would prove more graceful if he did not impose a condition that would have so prejudicial an effect as would be the case if the recommendations of the two committees he had referred to were disregarded.

committees he had referred to were disregarded.

Lord Cranbrook—The question, of course, so far as it can be considered will be considered, and I quite agree with 5 in Federick Brinned lihat nobed you predict what may be done one, but which may possibly have to wait. But in the meantime I can sature you that the interests of science will be most carefully considered, and that we will do what we can in order to further them.

Prof Story-Maskelyne, having thanked Lord Cranbrook and Mr Goschen for the hearing that had been given to their

views, The deputation withdrew

We have received the following communication on this subject .-

Sir,—The curious admissions made by Mr. Goschen to the deputation which waited upon him and the Lord President indeputation which wanted upon min and the solution dicate very clearly that we have, in the present muddle touching the site of the Art Gallery, another of those instances in which see and or one are susiety, another or those instances in which we suffer from the system, or, rather, want of system, which is characteristic of the relation of Government to science, and from the absence of sclennife knowledge in those branches of the public service by which matters of the highest scientific moment are settled. A reference to some of the facts will, I think, show this very clearly.

The particular site which has been allocated by the Government in this way for the purposes of an art gallery forms part of a piece of land which, as is well known, only last year was deliberately purchased by the same Government for scientific purposes—to be quite accurate for "acience and the arts". purposes—to be quite accurate for "science and the arts"— that is, science and its manifold applications. The space of ground thus purchased was less than half the space alloited to the Natural History Massium! I say deliberately, because the pur-chase of the land in 1890 had for its object the carrying out of one of the recommendations of the Duke of Devonshire's Com-mission, which dates from the year 1874—namely, the crection of a Science Massium.

of a Science museum.

This object so warmly commended itself to the Royal Commissioners of the 1851 Exhibition that in 1876 they offered the land on which the Imperial Institute is now being erected and a sum of £100,000 towards its realization

Few acquainted with the

manners and customs of our Government Departments in relation to science will be surprised to hear that this magnificent offer was refused; and it is to prevent a like disastrous mistake being now made that the strong memorial was presented to Lord

oow made that the strong memoral was presented to Low-Salbary.

Salbary.

S uon and uses.

This was the ideal recommended to the Government by the Duke of Devonshire's Commission in 1874, and such is the ideal now being carried out by several of our provincial Colleges
As all Londoners know, at present the Science Schools and the collection of scientific apparatus, which are both necessary for the realization of this scheme, are placed one on the east side of Exhibition Road, and the other chiefly in the Western Galleries. If the apparatus is employed in teaching, it must necessarily be transported about a quarter of a mile and back from the one to the other. And this accounts for the strange processions occasionally met in the neighbourhood of the Museum

carrying delicate apparatus along the street alike in wet and dusty When the new piece of land was purchased last year on the When the new piece of land was purchased last year on the recommendation of a very strong Treasury Committee, it was naturally expected that, as the overcrowded state of the existing school buildings rendered immediate action imperative, plans would be at once drawn up for an extension in the closest

possible contiguity with the present building—that is to say, on the part of the newly-acquired plot immediately fronting it It was also believed that the Science Museum would be built in close and organic relation with the new laboratories, and that a scheme would be initiated which would supply pressing needs, and could, in course of time, be developed into the ideal institution which has been sketched.

These plans, to the carrying out of which the friends of science confidently looked forward, would be rendered absolutely futile by the grant for art purposes of the particular plot the altenation of which from the use for which it was purchased will render the objects of its purchase nugatory.

All hope of a compact site, therefore, for the future worthy representation of physical science would disappear as the result of this action of the Government

e public have a right to know who is responsible for this, and how far the scientific officers of the Science and Art Department have been consulted If they have in any way been consenting parties, it seems probable that they will have a mauvais quart d'heure with their scientific brethren who have signed the memorial and who attended the deputation; if they have not been consulted, the whole transaction is a disgrace to our administrative system.

An idea of the impasse in which this decision has landed matters scientific at South Kensington was to be gathered from one of Mr. Goschen's replies as to the makeshift arrangements at first proposed :-
(1) The second half of the Science Schools is to be built

somewhere at the back of the new Art Gallery This at once prevents all close relationship between the two halves of the same institution.

prevents all close consumant between the two navies on the control of the control

are to be widely sundered, while any organic connection with the Science Museum is to be rendered impossible.

I do not think, Sir, I need occupy any more of your space with recent history, the whole question stands thus .--

(1) In our museum system Art, Antiquities, Literature, and Natural History are magnificently provided for (2) Science is not provided for at all in any permanent

(3) During the last twenty years Royal Commissions, Treasury of Departmental Committees without number, and deputations, and Departn

and Departmental Committees without number, and deputations, where pointed out this gap, where pointed out this gap, which is a simple property of the Exhibition of 185; sold cheap, a plot of land to be used for this purpose alone (5) The plot is less than half of that on which the Natural History Museum stands

(6) The Government now barter away a large portion of this small site for a mess of pottage age I am, Sir, Your obedient servant, F.R S

MOTES

THE ladies' souds of the Royal Society will take place on Wednesday, June 17

On Tuesday the Convocation of the University of London considered the Draft Charter drawn up by the Senate A resolution to the effect that the scheme should be approved was moved by Lord Herschell, seconded by Sir Richard Ousin, and supported by Dr Pye Smith Mr Bompas, Q C, Mr. R H Hutton, and others spoke on the other side. In the end the scheme was rejected, 461 voting against it, and only 197 recording their votes in its favour The whole subject needs to be thoroughly reconsidered, as the question of the higher tenching, one of the points first insisted on, seems to be dropping out of view. To educationists this is, of course, the really important element of the subject, and it cannot be for ever tolerated that the existence of an Imperial Examining Board, because it has been wrongly named, should prevent the largest city in the world from securing educational advantages which have for centuries been possessed by many a small German town

THE Government of New South Wales have granted for the purposes of the Sydney Biological Station a plot of land of two acres on the north shore of Port Jackson at a part where the littoral fauna is particularly rich, and where the conditions are in other respects highly favourable. The Royal Society have made a grant of £50 towards the cost of the proposed new

Tite annual meeting of the German Ornithological Society is being held this year at Frankfort, and the attendance is some what larger than usual, as several ornithologists have stopped at Frankfort on their way to the Congress at Budapest. The subject of zoological nomenclature was considered on Tuesday, when a discussion on the rules proposed by Dr Reichenow and Graf von Berlepsch ensued. The question will be further considered at the forthcoming Ornithological Congress at Budapest, where Dr Reighenow will be the exponent in the systematic

THE Australasan Association for the Advancement of Selence has published the Report of its second meeting, held at Melbourne in January 1890. The volume is edited by Prof. W Baldwin Spencer No one who glances over the volume can fail to recognize that the Association is likely to exercise a most important influence on the development of scientific research and thought among our kinsfels in the Australasan colonies.

The Ealing Microscopical and Natural History Society, of the which the Rev. of Hendow is Presiden, has issued its Report and Proceedings for 1850. The Committee are able to record that the work of the Society proceeded quelty has testedly on the lines laid down in previous years, the evening meetings, the executions, and the conversation-having all been held in their appointed seasons, and having had a full measure of success. Among the subjects brought before the evening meetings were "Adventures in Siberia," by Mr. H. Seebohn; "The Natural History of Malix," by the Rev G. Henslow; "Distorns," by Mr. E. M. Nelson; and "A Gossip on Mush-rooms and Toodstoots," by Dr. M. C. Cooke

DURING the last fortnight, according to the Caro correspondent of the Times, there have been in Upper and Lower Egypt large swarms of locuts, which have caused much alarm. Egypt large swarms of locuts, which have caused much alarm, sait is believed that they originate from eggs laid to the country last year. The damage done to the young maze, sugar, and cotton is an yet integration; though some individual growers have had to re-row cotton patches which had been devastated. The provincial Mudits have received orders to do everything in their power to secure the extermination of the locusts. The correspondent suy that this is the most serious respersance of an old Egyptian plague that has been recorded for about forty years.

A CIRCULAR relating to certain alterations in the Science and Art Directory for the session 1891-92 has been issued to NO. II24. VOL. 44

managers of schools of science and art by the Lords of the Committee of Council on Education. The following is an outline of the alterations, so far as they refer to science, or to science and art together -(1) Subject 6-Theoretical Mechanics-will be treated in two subdivisions: (a) the mechanics of solids, and (b) the mechanics of fluids-liquids and gases-payments being made on each subdivision as a separate subject. Subject 8-Sound. Light, and Heat-will be treated in three subdivisions in the advanced and honours stages, which may be taken, and will be paid upon, separately The elementary stage will still include all three subjects, but the syllabus will be curtailed and rendered easier, especially in "Sound" (2) These subdivisions will not be considered as separate subjects in the interpretation of the rule which limits the number of subjects on which payments may be made on a student in any one year (3) The number of National Scholarships in science to he competed for each year will be increased from 14 to 22 (6) In both science and art, the prizes of books, as distinguished from certificates, will be largely reduced in number, and only given in competition, those prizes which are now awarded simply on the student attaining a certain standard of excellence in the examinations being abolished. The time has passed when such prizes from a central authority, which entail a disproportionate cost and delay in administration, were justified by the necessity for stimulating science and art schools, and the Lords of the Committee of Council on Education are of opinion that the scholarships which will be substituted for them will be more useful. They trust that those interested in education in the several localities will themselves provide prizes of books for deserving students which may be useful to them in their studies

ACCORDING to the Indian papers, a persistent effort is being made by the Geological Department of the Government of India, in association with the Burman Government, to explore the tip resources of Tenasserim. The flourishing condition of the almost adjacent Malay States of Perak and Selangor, which are under British protection, is mainly due to the income derived from tin royalties. A year ago an expert was borrowed from the Straits Settlements and placed in Tenasserim under Mr. Hughes, of the Geological Department. The party has this year been joined by Dr Warth, the officer who did very good work for the Government in the Punish salt mines; and Dr. King. the Director of the Department, has left Calcutta for an inspection of the survey operations which have been conducted during the last twelve months. It is now two years since the Chief Commissioner of Burmah sent a special officer to report on the tin mines of the Straits Settlements, and the present explorations are being conducted in pursuance of the recommendations then made.

A PASSAGE in the correspondence of Leibultz and John Bercoult, to which Prof Hellmann has recently called attention in the Meteorologicale ZeateAry/I, indicates that Leibultz concived the dean of the ancroid borneter, which was fire tyracticulty realized by Vids in 1847, I Bernoulli, early in the eighteenth century, was considering the phosphorescence of mercury in the boroneter, and the possibility of making a new seriescent in the state of the possibility of making a new seriescent and such the dear of a baroneter for traveller; and Leibultz tells him he had thought of a portable baroneter, without mercury, in which a metallic case should be compressed by the weight of the sur. A bidder, or leather case, which he also suggested, Bernoulti condeted would be too hyproscopie.

MESSES, MACMILLAN AND Co. have just published "Natural Selection and Tropical Nature—Essays on Descriptive and Theoretical Biology," by Mr. Alfred Russel Wallace. The volume consists mainly of a reprint of two well-known volume

of essays—"Contributions to the Theory of Natural Selection,"
and "Tropical Natura and other Essays," Several essays have
been either wholly or in part omitted. On the other hand, the
sattor has included essays on the antiquity of man in North
America, and on the debt of science to Darwin, which have
billeto been accessible only in the periodicals where they
originally appeared. The text has been carefully corrected, and
some important additions have been made

A SUPERAMENT to Dr. T. Luder Bronton's "Text-book of Pharmacology, Therapeutes, and Materia Médics" has been usued by Mesers. Macmillan and Co. It presents the additions made in 1890 to the Bruths Pharmacopenis of 1885, although the medicanal substances contained in the British Pharmacopenis of 1885, are connected in the body of the work under the natural davanous of the muneral, vegetable, and annual kingdoms to which they belong, the author thinks it is easer to remember the additions by grouping them together according to their uses. A complete alphabetical list of them is also

A "BOTANICAL ADDRESS BOOK" has been issued by the well-known I cipzig publisher, Wilhelm Engelmann It contains a list of living botanists, and of botanical institutions, societies, and periodicals

F. A. Brockhaus, of Leipzig, has issued a catalogue of scientific works which are offered for sale at his catablishment, It includes, besides books, a large number of scientific periodicals and the publications of many learned societies.

THE 92nd and 93rd Parts of the "Landerkunde von Europa," edited by Alfred Kirchhoff, have been published They present an excellent account of various parts of the Balkan Peninsula

WILLING's (late May's) useful "British and Irish Press Guide" for 1891 has been published. This is the eighteenth annual issue

THE first number of a monthly journal for civil, mechanical, and electrical engineers, was published last week. The new journal is called the Engineering Review, and is edited by Mr. H. C. E. Andrée and Mr. Edward Walker.

AT the meeting of the Linnean Society of New South Wales on March 25, the Rev. Dr. W Woolls read a paper on the classification of Eucalypta. After critically reviewing the characters of Eucalypta which have, from time to time, been made use of for classificatory purposes, more particularly those of the anthers and of the bark as set forth in the anthereal and cortical systems of Bentham and Maeller, the author suggested the probable value of a dasafication based on the characters of the fruit—nuch as shape, position of the capsules, the number of cells, and the appearance of the valves, &c.

CAPTAIN PETERSEN, of the Swedish barque Eleanora, noted a submarine earthquake in the volcanic region of the Atlantic west of St. Paul Rocks on March 13 between 7 and 8 p.m. According to a statement in the printed matter prepared for publication on the Pilot Chart of the North Atlantic Ocean for the present month, the ship was heading north-west, going about 3 knots, with a light easterly wind and calm sea, when a noise was heard on the port side, like a heavy surf, and almost immediately the sea began to bubble and boil like a huge kettle, the broken water reaching as high as the poop-deck. No distinct shock was felt, but after the disturbance struck the ship she continued to tremble as long as it lasted. After about an hour it ceased for an hour, and was then followed by another similar disturbance. A bubbling sound was all that could be heard, and the water appeared foamy, but it was impossible, on account of the darkness, to say whether it was muddy. The next day weather and sea were as usual. Position at 8 p.m. lat. 3° 47' N., long. 42° 03' W. The region from St. Paul NO. 1124, VOL. 44]

Rocks to and including the Windward Islands is especially subject to earthquakes, and reports similar to the above are often

AT the ordinary meeting of the Institution of Civil Engineers on May 5, Mr. William Langdon read an interesting paper on railway-train lighting. He pointed out that the main questions to be determined were whether electricity was safe, trustworthy, and less costly than other illuminants. The fact that electricallyhighted trains had now been running for a considerable period without accident appeared to him conclusive evidence of its safety, and experience had shown that there was no reason to doubt its trustworthiness where efficient provision had been made; and he believed that when the cost of applying any of the illuminants, whether oil, gas, or electricity, to a complete railway system was taken into account the latter would be found the most economical Regarding electricity as the illuminant which would, at no distant date, be universally employed for train lighting, Mr Langdon suggested the desirability of arriving at a common basis with regard to the following fundamental points; (1) electrical system, (2) form and position of the electrical couplings, (3) pressure of current. Unless this was effected it was to be feared that unnecessary difficulties might be created by the diversity of the plans adopted

MR C. I. HANSSEN, a civil engineer of Copenhagen, has proposed a new international system of measures and weights, to which he invites our attention. He hopes that England will adopt his system, and that then the United States and Russia will follow, and thus the new system would become entirely international. Mr. Hanssen proposes that the English foot should be increased in length by about 1/2500th part of its present length (from 1 00000 to 1 000403), the pound avoir dupois, the ounce, and the imperial gallon, remaining unaltered, Tre cubic foot, as Mr Hanssen states, would then contain exactly 1000 ounces of distilled water at 4° C; and its inter comparison with the metric units of weight, length, and volume, would become apparently easy. We fear, however, that there is little hope in this country of introducing any such new system As Mr Chaney has indicated in his report on the Metric Conference, there are only two things possible in the metrology of this country · either to adhere to the present Imperial system, or to introduce the metric system. No half-way or modified Imperial system, such as Mr Hanssen would propose, appears to be possible.

THE Deutsche Seewarte has published, in vol xiii of its Aus dem Archiv, a paper by Captain C. II Seemann, one of the assistants in that establishment, entitled "Weather Lexicon an Index to the European Weather Charts from 1876-1885." The author considers that the principles we at present possess for forecasting the weather-e.g. Buys-Ballot's law, the relation of the tracks of depressions to the distribution of pressure and temperature, or the dependence of the lower air currents upon the upper currents-are not sufficient for the purpose, and he has made an index of the various similar types of weather-charts He has calculated the barometrical differences which occur each day in three directions (1) from Hamburg towards the northwest (Stornoway); (2) from Hamburg to the south-west (Biarritz); and (3) from Hamburg to the north-east (Helsingfors), and, by knowing the difference for any day, a reference to a table of such differences shows the dates of other charts with similar conditions, so that, by selecting one which appears most suitable to the present conditions, we may judge of the probable weather from that which actually followed that particular type. In the paper in question, only barometer and wind have been taken into account, the distribution of temperature would, of course, have great influence upon the changes of weather, but the author preferred to postpone the consideration of that element in this primary classification.

In the new number of the Journal of the Bombay Natural History Soclety, Lleutenant H. E. Barnes continues his interesting papers on nesting in Western India. Speaking of housesparrows, he says that no amount of persecution seems to deter them from building in a place when they have once made up their minds to it. At Deesa, he found that a pair had built a large nest in the antiers of a samhur in the verands. Another pair made a nest in the soap-box in the bath-room, and although the nest was destroyed several times, they would not desist, and at last, "from sheer pity," he had to leave them alone. The most peculiar case was when a pair had a nest in a bird-case hanging against the wall, just above where the "durzi" sat all day working, and close to a door through which people were passing in and out continually. The door of the care had been left open, the previous occupant having been transferred elsewhere. Not only were four eggs laid, but the nestlings were reared, although the cage was frequently taken down to be shown to visitors. Once the eggs were nearly lost, a boy having taken them out. The fuss made by the birds led to the recovery of the eggs. The author has a curious note on another peculiarity of sparrows, "I have often," he says, "had to turn the face of a looking-glass to the wall to prevent them from injuring theniselves, for immediately one of them catches a glimpse of himself in it, he commences a furtous onslaught on what he imagines must be a rival, and, if not prevented, will continue fighting the whole day, only leaving off when darkness sets in, recommencing the battle at dawn the next day. I once tried to see how long it would be before the bird gave in, but after two days, seeing no likelihood of his retiring from the unequal contest. I took pity on him and had the glass covered The bird did not seem in any way exhausted, although I do not think that he had a morsel of food for two days."

Some remarkable electrical phenomena accompanying the production upon the large scale of solid carbon dioxide are described by Dr. Haussknecht, of Berlin, in the current number of the Berichte of the German Chemical Society In order to obtain large quantities of solid carbonic acid it is found most convenient in practice to allow the liquid stored in the usual form of iron cylinder to escape into a stout canvas hag, best constructed of sail-cloth or some such strong fabric, instead of the usual lecture room receiving apparatus, the cylinder being inclined from the vertical so as to permit of a ready and uniform ext from the opened valve The liquid under these circumstances issues at pressures varying from 60-80 atmospheres, and a compact snow-like mass of solid carbon dioxide is formed in the canvas receiver, owing, as is well known, to the extreme lowering of the temperature of the liquid due to its sudden expansion and the accompanying absorption of heat When the experiment is performed in the dark, the canvas receiver is seen to be illuminated within by a pale greenish-violet light, and Dr. Haussknecht states that electric sparks 10-20 cm. long dart out from the pores of the cloth. If the hand is held in these sparks the usual pricking sensation is felt, similar to that perceived on touching the conductor of an electric machine at work. Dr. Haussknecht further states that the phenomenon is very noticeable in the dark whenever there is a leakage in any portion of the compressing apparatus or the manometers connected therewith The reason assigned for this development of statical electricity is similar in principle to that usually accepted in explanation of the hydro-electric machine of Sir William Armstrong. As the liquid carbonic acid is issuing from the valve it becomes partly converted into gas which is violently second through every pore of the canvas Moreover, carried along with this stream of gas are great quantities of minute globules of liquid, which are brought in forcible contact with the solid particles already deposited. Dr. Haussknecht therefore considers that the electrical excitation is due mainly to the violent friction between these liquid globules and the solid soon. It is represental for the successful reproduction of these electrical phenomens that the carbon disorded should be absolutely free from admitted air; that prepared striftically yielding much finer results than that obtained from natural values, which later contains considerable quantities of air. The luminosity is not generally developed in the interior of the receiver until a curat of solid carbonne and o'g-1 cm. thick contains the contains of the co

THE additions to the Zoological Society's Gardens during the past week include two Brown Capuchins (Cebus fatuellus & d), an Ocelot (Felts pardalis), a Coypu (Myopolamus coypus), two Ring-tailed Coatis (Nasua rufa), two Cayenne Lapwings (Vanellus cayennensis), seven Burrowing Owls (Spectyto cumscularsa) from South America, presented by Mr. James Meldrum. a Pig-tailed Monkey (Macacus nemestrinus 9) from Java, presented by Mr. C. Powell : a Common Hare (Letus en uneus). British, presented by Mr. H. T. Bowes, three Pintails (Dofila acuta & 6 9), European, a Mandarin Duck (Ax galericulata 9) from China, presented by Mr G. F. Mathews, R N , F Z S , a Common Bon (Bon constructor) from South America, presented by the Directors of the Museum, Demerara; two Cheer Pheasants (Phasianus wallachu & 9) from Northern India. twelve Common Teal (Ouerquedula crecca, 4 &, 8 9), European, purchased; a Viscacha (Lagostomus truchodactylus), a Red Kangaroo (Macropus rufus), born in the Gardens

THE IRON AND STEEL INSTITUTE.

ON Wednesday and Thurday of last week the annual spring meeting of the fron and Steel Institute was held. The gathering was announced to exceed over Friday also, but for meeting, the second day's proceedings were so hurried through that all the basiness was disposed of by half-past one o'clock on the second day, no less than surpers Sent states at the one test second day no less than surpers Sent states at the one test second day no less than surpers Sent states at the one test second day of the meeting might almost as sell have been dayened with and copies of the papers given to members to take home to read at their feature. It is seldom that we have been sent to be sent t

abolder, not resistent apparently using only anatoms that the should be no fatesmon to protoning the proceedings, should be no fatesmon to protoning the proceedings. In the manufacture of wer material in the United States, by Mr W. H. Juques, of Bethlehem, U.S. A., on test for sted used in the manufacture of artillers, by Dr. Wm. Anderson, Director Central Ordinance, on certain promotive measurements and central off-ordinance, on certain propositions, or a common promotive measurements and on the changes in loss proton by Frof. Robert-Austria, F.R.S., on the changes in loss proton by Frof. Robert-Austria, F.R.S., on the changes in loss proton by Frof. Robert-Austria, F.R.S., on the changes in loss proton by Frof. Robert-Austria, F.R.S., and the composition of furnace charges, by Mr. H. C. Jenkins, on economical publing under by Prof. Thomas Turner, Birmingham is on the mero structure of steel, by Mr. Turner, Birmingham is on the mero structure of steel, by Mr. M. C. S. Tarks. There were there other papers which were not read.

not read. Upon the members assembling in the theatre of the Institution of Civil Engineers, which was lent for the occasion by the Council of the Later Society, according to their hospitable Council of the Later Society, according to their hospitable chair. After the usual formal business had been transsiered, the new President, Sir Frederick as lade, F.R.S., was dupli installed, and at once proceeded to deliver his inaugural address. Sir Frederick is also this year President of the Buttish Association, Present the Council of the Section of the Council of

ing a wide range of subjects and a long span of time. The duration of Sir Frederick Abel's official life has been long, exceptionally long for the years he has lived, for he obtained employment in the Government service at an early age. It was shortly after the outbreak of the Russian War that he succeeded the illustrious Faraday in the Professorship of Chemistry at the Royal Military Academy, and since then he may be said to have seen almost the whole history of the hirth and subsequent have seen almost the whole history of the hirth and subsequent growth of applied sceneet in consection with the industries of growth of applied sceneet in consection with the industries of us in his address, bose who, in this country, appraised, at their proper value the services which the analysical and scientific chemist could render to the irron-matter and manufacturer of analysis. Was just in process of application, volumetries analysis was altogether in its infancy, and spectroscopic analysis was not rendered to the mediatory operations in the Aresual at war dreams of . The mediatory deportation of the Aresual at Woolwich were limited to the production of small castings of Woolwich were limited to the production of small cassings of brass for fittings of gui carriages, and to the casting of bronze ordance for field service. Our supplies of cast-tron ordance to the cast of the cast of the cast of the cast of our most consent ones when the cast of the cast of the cast of the supplied from private works. What Woolwich has become since those days—and in spite of its falls of administration it a something of which the country may be proof—and how large parts. If reference, has borne in this development, most of our a part SIF Federick has borne in this development, most or our readers must be well aware. In those days our most powerful guns were 8-inch smooth bore 68 pounders of cast-iron, weigh ing 95 hundredweight, and fired with a charge of 18 pounds of powder. Now we have the 110 ton breech loading rifled gun, built up of 14eel hoops and tubes, the calibrate of which is 16; built up of steel hoops and tubes, the calibre of which is "16 inches, and which throws steel projectle weeghing 1800 pounds that the 110-ton gui is in advance of its time—our mechanical skill and engineering knowledge not pet being sufficient to properly carry out the design—it would be difficult perhaps to find a more saming resumple of the application of scientific principles more saming aroung the time of the supplication of scientific principles considered the supplication of the deviation of the deviation

Woodwood use a compared to the state of the completed their work. Shoust use commenced, it will do much towards lightening the work of those who have to compare much properties. The state of the state of the work of th is astuafactory to learn that "the systematic appuration of sorby's system of microscopic examination of perpared surfaces of steel and iron is continually extending at the German works, and that many series of experiments have demonstrated that by this system of examination characteristic features of grades of the system of examination characteristic features of grades of the system of the iron may be discovered, physical differences co-exist iron may be discovered, physical differences co-existing with identity of chemical composution explained, and evidences of between grounds of disastern obtained." A very nateracting subject nest occupied a place in the address. This was the self-destruction, if one may use the term, of steel projectiles by the development of crucks. It is well-known that steel prothe development of crucks. The steel known to be a steel prothe development of the steel pro
the steel protection of the steel pro
the steel protection of the steel protection of the steel pro
the steel protection of the steel protection of the steel pro
the steel protection of the steel protection of

place. The cause doubtless is the surface treatment which the shot is subjected in order to get the requisite hardness, and which leads to internal strains being set up. In one case mentioned in the address the head of the up. In one case mentioned in the address the head of the projectille had been thrown to a distance of many feet by the volcent spontineous reputer of the metal. The importance are proposed to the proposed to the projectile and the projectile and the projectile, which had to be the behaviour of chrome steel projectile, which had to be the behaviour of chrome steel projectile, which had to be the behaviour of chrome steel projectile, which had to be the behaviour of chrome steel projectile, which had to be the behaviour of chrome steel most behaviour to a distribution of the projectile and the subject Six Frederick referred to a previous report in which he dwell upon the effect of times in establishing chemical equilibrium in masses of metal. He slio quoted a letter written to him by Thomas Graham, when blaster of the Min, in which was discussed the tendency to the development of cracks in tempered steel dies, and stating that in the Mint it was generally considered steel dies, and stating that in the Mint it was generally considered that if such dies were kept in soree for a year or two, they became less apt torrick when in we, and council more preceded to the property of the property of the considered in the manufacture of steel ordinance, and an in-tance was given by the lecturer of the tube of a large gun which had fired three proof rounds. A circumferential crack. was found to have become developed in the front threads of the was found to nave become developed in the front threats of the breech screw, and, upon removing the jacket from the tube the crack extended forward along the chamber and into the rifting When the tube was placed in the lather, with a view to cutting oil the injuriel portion, the crack suddenly developed itself with a the mysrel portion, the crack suddenly developed iterit with a doubt report, and final along to within eight feet of the muzile, a spral crack at the same time ran completely round the tube, which fell at two upon removal from the lather. This metance will strengthen the hands of those who are opposed to maintaining the parts of a steel gain, and Sir Frederick's own hardening the parts of a steel gain, and Sir Frederick's own hardening the parts of a steel gain, and Sir Frederick's own the steel of the stee exercised in the case of particular qualities of steel is that of developing minute fissures or cracks in the metal, either super-ficially or in the interior of the mass. This cannot, of course, be rectified by any annealing process, and it is still a question, to be determined by the teachings of experience and the result of investigations, whether any definite or reliable modifications in the composition of steel used for guns, tending to secure the desired combination of hardness and tenacity may not be introduced, with the result that a method of treatment of the metal may be discarded which, however carefully applied, and however may be discarded which, however carefully applied, and nowever efficient the means adopted for reducing or neutralizing its possible prejudicial influence upon the physical stability of the parts of which ag un a built up, carries with internet elements of uncertainty and possible danger." Dr Andreno's remarks on the subject of orli-interienting inhould salo be read in connection on the subject of orli-interienting inhould salo be read in connection the whole, perhaps, it would not be rash to predict that the development of the product of t days of this process are numbered in connection with the manu-facture of steel ordnance for Her Majesty's service. For a long time many of our best authorities have been opposed to it. We have not space to follow the address into the subject of

the effect of silicon in cast-iron General interest in this matter was aroused a year or two ago by a paper read before the Iron and Steel Institute by Thomas Turner, of Mason's Coilege, and since then the investigation has been followed up by and since then the investigation has been followed up by German experimentalists, with a general result that, under certain conditions, it is concluded that silicon will contribute to the production of dense and homogeneous castings. The following passage from the address speaks for itself. It would be well it it could be printed and distributed to every

British iron or steel maker :-

Bruths iron or steel maker:—
"The absolute dependence of the development of new metallungic processes upon the results of the labofits of the analysis,
"The absolute dependence of the declared the analysis,
and the thoroughness with which this all-important fact is
appreciated by the German metallungic establishments, afford
were occasion for a reguella recognization of the datasets which
were constant for a reguella recognization of the advantages afforded by the constant parsent of scientific
search, and the thoroughly effective, systematic, and direct
duly operations at works of the scientific investigation to
the

the to daily that it industries which the genine of midrodaul

Englishmen, possessed of exceptional powers of applying to important practical purpose the results of research, have created and have developed to an extent foreshedowing their high importance, gradually passed out of our laxeds through the farmed the should be considered to the first three powers are made the shoulded dependence of progress in and industries upon the constant pursuit of chemical research into the far-reschiling and continuity spreading raunfactions of organic chemistry. Thus, in fields of work, where, in days past, and even of late, our modurativit chemists have been content to pursue even of late, our modurativit chemists have been content to pursue even of late, our industrial chemists have been content to pursue their attempts at progress with the co-operation of one or two young chemical assistants, small armies of highly-trained chemists, who have guned academic honours, and have won their pursues the content of the ever and anon, they result in some fresh discovery of great tech nical importance and high commercial value Similarly elaborate

nical importance and high commercial value Similarly elaborate and comprehensive arrangements now exist at important German fron and steel works for systematic investigation and comparison finaterials of products and processes " but for five five with the product and processes". We must hurry over the remaining parts of Sir Frederick's "ddress, and can only mention some of the chief subjects touched upon, referring our readers to the Proceedings of the Institute for faller information. Thus we find the following matters occur. for fuller uniformation. This we find the follows of mattern course propagation to the presence and effect of nutropen in iron; the state in which carbon exists in steel; Omnoni's study, by means of the Lo Chretcher promoter, of the slow cooling of and the existence of two silotropic forms of iron, the effect of asimumum ir nor; Hadfeld's researches in connection with manganess steel; the progress of nuclei steel, and the unterthe section of carbon existence which is the steel of t Interesting and characteristic address

Only one paper was read on the first day of the meeting This was Dr. Anderson's contribution on tests for steel used in This was Dr. Anderson's contribution on tests for steel used in the manufacture of artillery. The manonement of a contri-bution on this subject by the Director-General of Ordanoe Fectores had caused a good deal of interest both among the screenite and manufacturing members of the Institute, more specially as it was known that the Government sutherites had been supported by the order of the property of the angular bowever, the meeting was a little too early, so far as Dr. Anderson's renow was concerned, for the new regulations nowever, the meeting was a little too early, 80 ara as Df. Anderson's paper was concerned, for the new regulations have not yet been officially published, and, until they are, it is against official etiquette, if not official artiles, that they should be made known. The paper was therefore very like the play of "Hamtlet" with the Prince of Demank Left out, and bore play of "Hamlet" with the Frince of Denmark left out, and bore evidence of having been brought forward rather with a view of fulfilling a promise than because the author had anything new to advance. It was not Dr. Anderson's fault that his paper was robbed of its chief interest, and certainly the thanks of the robbed of its chief interest, and certainly the thanks of the Council were due to him for good naturably allowing it to stand on the programme. Nowthbranding what we have said, the apper was very interesting, but as we hope to be any I. Anderson again on the subject, when the official veto has been removed by publication of the new tests, we shall treat the matter briefly. It is first pointed out little that the mechanical properties of steel, and the standard of the standard of the standard of the standard of the contraction of the standard of the standard of the standard of the contraction of the standard of the standard of the standard of the contraction of the standard of t and of alloys generally, are anected in a remarkable manner by extremely minute quantities of substances, by the relative pro-crease rapid changes of temperature, which influence dissociation and reveal their effects by recalescence; indicating, to a less degree, allotropic changes in some or all of the components. Chemical sanshysts sufficiently minute to detect even traces of Chemical manyas numerany minus to detect even traces of overly. Support of the control of the c

so far, at any rate, as ordinary lugredients are concerned. The suther thinks it is not sufficiently realized that metals are in-compared to the control of the your could. Like its and water, steel and cast-iron have a greater volume in a solid than an the liquid state, and, therefore, red-volume in a solid than an the liquid state, and, therefore, red-mass although, it should be addreft, cold cast-rorn will at first also it as a though, it should be addreft, cold cast-rorn will at first also it as a farey red. This was shown by the well-known as a shount to a cherry red. This was shown by the well-known float when it has acquired a sufficient degree of heat to hung it about to a cherry red. This was shown by the well-known experiments of Mr. Weghtson, referred to at the meating. The manuser as which, during cooling, compressive stream of the state of definite compound of carbon and iron dissolved in an excess of definite compound of carbon and iron dissolved in an excess of tron, and as a facely subdivided carbon diffused through the mass, is considered, and the suthor expresses an opinion that the "apparently capricous behaviour of stell" is due not only to the internal stresses engendered by oil-hardening, but also to the circumstance that the chemical condition of the steel and its molecular structure are greatly influenced by comparatively slight errors of judgment, or by carelessness in the adjustment of the temperatures at which the operations are performed.

of the temperatures at which the operations are performed.
A discussion followed the reading of the paper, in which the
most interesting incident was Mr. Wrightson's description of
the experiments to determine the votume of east-iron at different
temperatures. Mr. Edmunds, of Woolwich, defended the
strictures and the stricture of the stricture

f manufacturing operations.

great satisfaction by prominent man over the man and common with the man and t centage of carbon from 0.1 to 0.2, the maximum tenacity is attained, not at 3300° C, but at a much lower temperature—about 1000°—below the melting point of iron oxide, which, moreover, attanes, not at 150° C. Jost at sunch lower temperature—about 100°—below the melting point of no node, which, meetors, necoting, the melting point of no node, which, meetors, percentage of carbon, this point of maximum tenselly apparently disappears almost entirely, the annealed metal having nearly as high a tenulic strength as the same metal which has been quenched in noil from any temperature ny to a bright to hardened metal became so hard and brittle that it could not be groped by the saw of the testing machine. It will be remembered by those who attended the meeting when Dr. Ball's lase to the same proper to the proper same properson of the the last paper read, that of Lieutenant Jaques, U.S.N., was of such a voluminous nature that it might better be described as a treatise, and is far beyond our scope, as may be judged from its

The autumn meeting of the Institute will probably be held at Birmingham.

THE ROYAL SOCIETY SOIRER.

THE soirdes given by the Royal Society become every year more pleasant. The one held on Wednesday, May 6, was in every sense most successful. We note some of the objects

THE RENUE AND THE KIRRE

AT Monday's meeting of the Royal Geographical Society, Major Claude M Macdonald, H M. Commissioner to West Africa, gave an account of a journey up the Benue and its northern tributary the Kibbé, in the summer of 1889. The its notratern utidutary the KIDE, in the summer of 1809. The Benue, we need scarcely say, as the great tributary of the Niger. Major Macdonald referred to the previous explorations of Barth and others, and to the fact that it has been maintained that a connection existed between Lake Chad and the Benue, by the overflow of the Shari on one side and the Kibb on the the overflow of the Snari on one side and the Aldre on the other. Major Macdonald has been the first to explore the Kibbe, After describing the ascent of the Benué, Major Macdonald went on to say that he and his party started on their journey up the Kibbé in the Royal Niger Company's stern-wheeler the

Brand, on August 21.

The Kibbé at its mouth is some 250 yards wide, while the Beaué is upwards of 600. The average depth of the Kibbé at this season of the year, nearly high water, is from 10 to 12 feet.

On both banks for the first five miles the country is flat and On oon names for the trist five miles the country is nat and well wooded, with patches of bright green grass, and looks very gamey, though owing to the high grass we saw no deer. A noticeable feature some five or six miles from the river is Mount Kane, a rounded hill, some 800 feet high, well wooded to its summit. This hill, from its isolated position, served as an excellent point on which to take angles for mapping purposes. Patches of cultivation were now to be seen on both banks, and Paules of cultivation were now to be seen on footh banks, and after two hours' attenuing the party passed the Fully willage of after two hours' attenuing the party passed the Fully willage of steamer or a white man, did not seem much disconcerted, and, when shouted to in their language, restrined the sultations in a very firently manner. On Angust 22 the Houst anchored of a McConsalt states, "that we had to deal with the purest-heed Falls we had seen so far. The crowd consisted atmost entirely of woman—by far the best-looking we had as yet seen on the west Equatorial Africa. They wore the usual piece of cloth would round ther bodies, leaving their arms and shoulders hore, and reaching down below the knee. Their features, in most cases, appression, and their expression may genile and modest, yet full of vivecity. They told us that the name of their village was Fram, and that it was governed by an anneal was trained to the training the second to the training training to the training training to the training trai

Shortlyafter this the steamer came to a deserted atrip of country, own fifteen miles in length, which was evidently the barrier between the Mahommedan and Pagan tribes it was of an undulating character, with isolated hills, and well wooded. The river was still about 100 yards wide, but commenced to be dotted with contracting and was in part were whallow with a sandy buttom.

sill about too jards wide, but commenced to be dotted with grassy jainds, now as an party weep shallow with a sandy bottom. Next day, as the istement advanced, the river narrowed gand made a sharp bend to the eastward, and approached a new state of the state of the

"The scenery now was very picturesque; to our right, i.e. the south of the river, some few yards from the water's edge, the mountains rose in some places quite abruptly. These mountains

were for the most part covered with green wany grees very pleasant to the eye. One of two streams trocked down the mountain side, forming now and again potenties westerfalls. The river had studently broadened out to a lake, or, more properly speaking, manh, some three miles long by two wide. The range of grawy mountains I have mentaoned run along the row of the seat and not have to the lake, as far as the eye could see in the direction of the Taburi mark (near the Shart river) was open and grayl undustaing, while from the western shores of the seat and entire the seat of the

and had the appearance of the country places of the nicher mahabitants of the village associated our more-ments with great curroutry. We asked to see the chief of the village, and after a good deat of palware, a man appeared attired in a very statered "tobe" or gown. He had something of the Falbe in his countenance, and was a tall fine man, though of rather worself to get what influences as a tall fine man, though of rather worself to get what influences are could out of him. It is said the name of the hig water we saw was Nabared, but that it was only a fourth that size in the dry season. The name of his willage was Kakea. The channel off the river as along by the mountains. He knew of the Tubun marsh, but had never as distant many days' journey. He knew of no other big water, but would give us a guide to show us the way. The people of the Nabaret district are possessed of calle, but no horses; they live principally on chairra, which they cultivate the propostion, of which we saw a dozen in the lack, though doubtless there may be many more.

"We took our guide on board and endeavoured to make for

PYCNOGONIDS

Den Norske Nordhavs-Expedition, 1876-78. XX. Zoologi-Pycnogonidea. Ved G. O. Sars. Med 15 Plancher og I Kart (Christiania . Grondahl & Sons, Bogtrykkeri. 1801.)

Studies from the Biological Laboratory, Johns Hopkins
University, Baltimore. A Contribution to the
Embryology and Phylogeny of the Pycnogomids
By T. H.
Morgan. With Eight Plates. (Baltimore The Johns
Hopkins Press, 1851.)

THE group of sea spiders, or the Pycnogonidea, was for a long time among the least known, though by no means the least interesting, of the divisions of the marthe invertebrates. Linness described a species as a Phalangium, placing it among terrestrial forms, and though a century and a quarter has passed since then, the problem of where to place these Pycnogonids cannot be said to be finally settled.

Within the last ten years or so, an immense advance has been made in our knowledge of the morphology, anatomy, and embryology of the group, thanks to the labours of Anton Dohm, who, in 1831, described the forms found in the Gulf of Naples, and of Hoek, who about the same date described the species found during the cruses of the William Barents and the Challenger During all this period opinions varied as to whether these forms should be placed among the Arachinds or the Crustacea, but apparently both the authors just referred to have agreed that the Pycnogonids should be placed with neither, but that they, with the Anachinds and the Crustacea, have come down the stream of evolution in parallel lines

To the evisting recent memoirs of these Arthropods, the splendid volume just published on the Pyrongoindea found during the Norwegian North Atlantic Expedition, 1876–78, by Prof G. O. Sars, adds, perhaps, from a morphological point of view, the most important of the recent publications on the group, for, valuable as beyond question are the structural and developmental details, a special knowledge of general morphological details is also needed for the convenient understanding and classifying of any group

The maternal at Prof. Sart's disposal was very large, and in addition he has made use of collections made by himself during many years back on the coasts of Norway, and also of some few forms sent to him by Dr. A. Stuxberg, which had been found in the Kara Sea during Nordenselbid's expedition A very great contrast is to be seen on comparing these northern forms with such a collection as that of Dohm from the Mediterranean. The great number of species belonging to the family Nymphondies is specially characteristic of the Northern Seas as contrasted with the Mediterranean, while again the Northern Seas as contrasted with the Mediterranean, while again the Northern Seas as contrasted with the Mediterranean, while again the Northern Seas as contrasted with the Mediterranean, while again the Northern Seas as contrasted with the Mediterranean while for the Mediterranean while specially challenging the season of the Mediterranean of the Mediterranean while special properties of th

In working out the classification of the group, Sars has found it necessary to treat the families in a somewhat more for hardening; the eggs being cut in parafin.

restricted sense than has been done by most of the previous writers, and has been obliged to increase their number While fully agreeing that the descriptions and even figures of the Pycnogonids given by the earlier writers leave much to be desired, and are as a rule even exceedingly defective, in some cases indeed being so bad as not to be intelligible, yet he thinks that some quite recent describers have rejected as bad a greater number of descriptions than with a little patient research was really necessary. Thus he finds it hard to believe that, while not a few species have been described from the Gulf of Naples, all the species described as found there by Dohrn, with one exception, should be new. Most certainly as regards the northern species we cannot sufficiently admire the pains which Sars has taken in working out all the imperfect descriptions and rough figures of our past recorders of new forms, with the result that he has succeeded in re-establishing many wholly forgotten or ignored species of Goodsir and others,

As regards the terminology used in describing the various parts, some, classing the Pythogonids with the Crustacea, adopted terms in use among the latter; while others, holding their affinity to be with the Arachinds, employed again a different set of terms. Dohn, to avoid the difficulty as regards the limbs, rejects all special terms, describing them as No. 1, 11, &c, sar uses a terminology the terms of which involve as little as possible of any homologous references.

Forty-three species are described and figured. Several of them are here fully described for the first time, though short diagnoses of them appeared in a preliminary report The fourteen genera are arranged in eight families. and these are grouped into three orders, the ordinal characters being based on the relations of the "chelifors" Thus in Order 1. Achelata, these chelæ are, except in the larval state, entirely absent; in Order 2, Euchelata, the chelæ are well developed throughout all the stages of life; while in Order 3, Cryptochela, the chelæ are present, as a rule, in the young stages (not alone in the larvæ), but in the fully developed condition they become atrophied or disappear. This arrangement no doubt will have to be modified so as to fit it to receive the very numerous forms from other parts of the world, but it is a first step in the right direction of an intelligent grouping of the genera

The second memour on our list treats of the Pycnogonids from a different standpoint, being a contribution to our knowledge of the embryology and phylogeny of the group, by T. H. Morgan, Fellow of Johns Hopkins University After a short allusion to the work of Dohm and Hoek, who have "placed the morphology of the order on a very firm basis," he proceeds to treat of the early stages of the embryology of the Pycnogonids, stages which have been practically unexamined, and a knowledge of which is needed to enable the relationship of the group to be guessed at.

The material for this work was collected at Woods's Holl Three genera, each with a single species, are to be found at this place—Pallene emplusa, Phoxichithdium maxillars, and Tanysiyhum orbiculars, and during july. August, and September, these were found carrying ova The alcoholie picto-sulphunc acid process was adopted for hardening; the eggs being cut in paraffin. The

eggs of Pallens were large, 0.25 mm., and well adapted for investigation. After a munte description of the early stages of development, the author considers that from them there is little or no ground for a comparison between the Pycnogonids and the Crustacea, certainly not with any esting forms. The multipolar delamination of the endoderm in the Pycnogonids has no homologue amongst the Crustacea, nor is there any special similarity in the formations of the organs. There seems to be not race of gastridation hise that in the Crustacean in the ontogeny of the group. And if there be reason for rejecting a relationship between the Pantipola lava and the other properties of the properties of the properties of the other properties.

Nor are there any specual affinitives between the insects and Pyringonous's but between these latter and Peripatus as atriking similarity is met with in the paired ventral structure organs, both in the structure and position of these, but for the present there is no proof forthcoming as to a real homology of these bodies. The process of the formation of the endoderm, as described by Heider and by Wheeler in insects, shows a certain resemblance to multipolar in insects, shows a certain resemblance to multipolar form than is shown by the Pyringondis. With these two exceptions there would seem to be nothing else in common in the notice of the two groups.

Lastly, as to a decision as to the relationship with the Arachnids, or as to their being an independent phylum While Dohrn and Hoek ably maintain the latter, though not agreeing as to the why in all details, yet the study of the early stages of the embryology has brought to light certain facts which lead the author of this memoir to believe in a community of descent between the two-The reasons for this belief are given in full detail, with difficulty admitting of abbreviation. The Pycnogonids form the endoderm by a process of multipolar delamination, which is shown in its simplest form in Phoxichilidium and Tanystylum, and in a more modified condition in Pallene. In no other group of the Triploblastica is a similar phenomenon found except in the Arachnids In the spiders the process is not so well marked but it Balfour's conception of the formation of the yolk nuclei be correct, then a direct comparison may be made between the two groups. The first trace of the embryo to appear in Pallene is a round opaque area at the spot where the stomodæum invaginates. In Schimkewitsch's recent account of the development of the spiders, he shows that the primitive cumulus in them is the place where the stomodæum invaginates; and in calling attention to the fact that the stomodæum of spiders in its earliest development is a triangular invagination, he actually compares it with the triangular invagination of the exsophagus of the Pycnogonids. It is also exceedingly probable that the early formation of the body cavity surrounded by mesoblast in the legs of spiders has an exact parallel in Pallene and Phoxichildium. In both Arachnids and Pycnogonids there are wellmarked diverticula from the mid gut into the legs. In both Arachnids and Pycnogonids the first pair of appendages are chelate, and in both this first pair is innervated from the brain; these facts alone, it will be remembered, were considered by Balfour to indicate a relationship

between the groups. Mr. Morgan was unable to find any post-oral ganglia for Pallene, but the first pair of appendages arises on the sides of the stomodæum and moves forward later In this respect, it compares closely with the spiders, and the early innervation of this pair from the brain itself may be regarded as a more abbreviated condition than what was seen (by Balfour) in the spiders. Metchnikoff's figures for Chelifer show the first pair of appendages to arise above and on each side of the proboscis-like upper lip, and if future investigation verifies Metchnikoff's suggestion that this proboscis is homologous, entirely or in part, to the proboscis of the Pycnogonids, as his figure seems to indicate, then does the whole development of the Chelifer show remarkably close resemblances to that of the Pycnogonids pair of ambulatory legs-the seventh pair of appendages -has been a stumbling-block in the way of an Arachnid relationship, and the attempts to solve the difficulty have been many. Here, again, Balfour's suggestion that this last segment and its appendages may represent the first abdominal segment of the Arachnids is of value, as we know that the embryos of spiders have rudimentary appendages on the abdomen In a second part of this memoir the metamorphosis of Tanystylum is described. and in a third part we have a very complete study of the structure and development of the eyes of Pycnogonids and a comparison with the Arachnid simple eyes, a comparison that seems to verify the relationship pointed out E. P W. in the first part of the memoir.

A TEXT-BOOK OF CHEMISTRY BASED ON THE PERIODIC SYSTEM

A System of Inorganic Chemistry. By William Ramsay, Ph D, F R S. Pp. 700 (London: J. and A Churchill, 1891)

OURING the twenty-five years or so which have elapsed since the recognition of the periodic law of the chemical elements as a valid relationship, the pronounced influence which it has exercised both on the aspect and aims of chemical science cannot be questioned. Whether in the prediction of undiscovered elements, or as an indicator of needful research, especially in the department of atomic weight estimations, it has met with signal success In connecting the physical properties of the elements themselves and of their compounds with atomic weight, it has opened up new fields of investigation, and thrown fresh interest into old ones Properties so widely different as those measured by refraction equivalent and breaking stress find an explanation, nowadays, in the magnitudes of the atomic weights.

As a mean's of classification, too, the success of the periodic arrangement has not been less striking. Indeed, to its power as an instrument of classification it owes its general acceptance in the first instance. When the ideas of Avogadro had become recognized, and by their means the old system of "equivalents" had been replaced by the true atomic weights, then the periodic arrangement resulted in a grouping of the elements so much in harmony with existing notions of their relationships, that the far-reaching power of the generalization could no longer be resisted.

The distinguishing feature of the book before us consists in the use of the periodic arrangement as a means of classifying the subject matter of inorganic chemistry. Here, the time-honoured methods of putting the facts and theories of chemistry before the student are set aside, and as the method adopted is novel to English textbooks, it may be advisable to consider its characteristics. After a short historical introduction, the author proceeds to describe the occurrence, preparation, and properties of the elements in the order in which they are found in the periodic table. First, Group II, metals of the alkalin earths, and so forth The descriptions refer, as far as possible, to the elements of the same group taken collectively.

The compounds of elements of the different groups with the halogens form the next part, and in the introductory portion the student meets for the first time with matter which it is customary to discuss at an earlier stage in the text-books; such matter as the distinction between element and compound, the use of chemical symbols, the gaseous laws, &c. The fourth part deals with the oxides, sulphides, selendee, and clillurdes, and under these headings are to be found hydroxide, whydrosulphides, &c., classed as compounds of the oxides with water, hydrogen sulphide, &c. Here, also, are treated the salts of the oxyacids, classed as double oxides, and compounds with the halogens.

Part v gives an account of the borides, carbides, and sclicdes, such of the hydrocarbons as are considered, and the organo metallic compounds occur in this part Compounds with the elements of the nitrogen group, including the cyanides, form Part vi. Alloys and amalgams are discussed in Part vii. The first chapter of the next part gives a short account of spectrum analysis and the rare earths. The second chapter is chiefly concerned with the criteria for fixing atomic and molecular weights, the Raoulir methods finding a place, and the last chapter is devoted to the periodic law. The closing part of the book takes up, manly with regard to the chemical principles involved, the manufacturing processes usually texated in the text-books.

It will be seen, as the author states in his preface, that the method adopted does away with the distinction between metals and non-metals; no special stress is land on the properties of acids as contrasted with bases; equal prominence is given to tare and more common substances; and the commercial importance of a substance or process and the commercial magnitude of a substance or process is not considered an argument for its special considera-

Such a work as this may be looked at from two points of view. Regarded as a systematic arrangement of the facts of inorganic chemistry, from which any desired information may be speedily taken after one has become a similarized with the method of classification adopted, its success is undoubted. The book is quite in touch with recent investigations, nothing of importance seems to be omitted from the descriptive portion, and, what is a recommendation to a large class of readers, the size of the book is not excessive. Whatever be the results of the system adopted, economy of space is assuredly deheved.

To the teacher or to the advanced student who wishes to use the book as a work of reference, or desires to

systematize his knowledge, it will be eminently useful. If, on the other hand, the system be regarded from the point of view of a basis for teaching, its construction from its very novelty must be open to discussion A method of teaching chemistry often employed may be said to consist in giving the learner in as easy a manner as possible the leading facts of chemical science with regard, in the first instance, more to the correct appreciation of the meaning of the facts themselves, than of the exact arrangement or classification of the same. To this end the student is led from the study of the chemical properties of commonly occurring bodies to the description of the elements contained in them, explanations of chemical terms being given as they crop up, or in short reviews at intervals not far apart. When the properties of the elements are being explained, their reactions with other elements have to be noticed, and hence it appears natural to describe the important compounds of an element after its own properties have been discussed The periodic system does not seem to provide the means for such a course of teaching, and this appears to us to be the main reason for its non-adoption in the text-

Indeed, the new method has little in common with that indicated above The entire series of the elements apart from their compounds are described, and chemical and physical terms are freely used without any attempt being made to define them till all the elements have been treated In fact, a few terms, as critical point and heat of formation, are used, but as far as we can see, not defined in the book Again, compounds containing a common constituent are classed together, but compounds of what may be taken as a parent element are scattered throughout the various groups Surely, in connection with this point, reasons similar to those which lead to the grouping of compounds containing the same element, on the new system, would hold for the old method of considering compounds. The position of the tron group of elements after the aluminium group and of the copper group-the last one described-may be taken as an indication that even in the author's opinion the periodic law does not in all cases indicate most clearly the relationships of the elements Such considerations as these must weigh with a teacher before he can adopt the system : during four years' experience, however, the author has had no reason to doubt its success.

The book is clearly printed, and the illustrations, though not very numerous, are for the most part new. The frequent use of vapour jackets in the apparatus represented is suggestive of the author's more recent contributions to scientific literature. The useful system adopted by Ostwald in his "Lehrbuch," of indicating the state of aggregation of a substance by the type, has been employed.

Setting aside the points which may be urged against the work as a basis for teaching, the penodic law, as expounded by Prof. Ramsay, does more than any other system of classification to put the matter of inorganic chemistry on a footing resembling that which holds for organic chemistry.

OUR BOOK SHELF

Eighteen Years of University Extension By R D. Roberts, M A. D Sc (Lond.), (Cambridge University Press. 1801)

THE University Extension movement takes so prominent a place among the educational influences of the age that a good account of the system has for some time been needed. This is supplied by Mr Roberts, who, first as needed. This is supplied by Mr. Roberts, who, first as lecturer, then since 1881 as assistant and organizing secretary to the Cambridge Syndicate, and since 1886 as secretary to the London Society, has had the best possible opportunities of studying the new method, and of forming a judgment as to its fitness for the uses to which it is He begins with an account of the origin and growth of the movement, then describes the character of the audiences, the reception of the idea by artisans, and the signs of earnestness displayed by various classes of students. Mr. Roberts also discusses the conditions of success, has a chapter on the consolidation of the work, and presents a summary of results. No essential fact be left on the minds of most readers probably is that those connected with the movement have done much to foster and to satisfy the desire of a very large number of persons for intellectual training. There are certain rules—some of them rather difficult—with which the system must be brought into accord if it is to be capable of further development; and these are stated with much force and precision in the present useful little volume

Evening Work for Amateur Photographers By T C. Hepworth, F.C S (London, Hazell, Watson, and Viney, Ltd, 1890)

In this book the author has written, in an interesting manner, a series of chapters relating to many points in photography that are generally found most useful to amateurs following are the subjects of some of the chapters. lantern entertainments, lantern-slides on gelatine plates, clouds in lantern pictures, frame-making, enlarging, photography by magnesium light. There are also two or three chapters on electric light, light by incandescence, and methods of making cheap batteries

The subjects are treated in a manner that makes the book well worth reading, and its value is increased by numerous illustrations obtained from photographs and

drawings by the author

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Neither can he undertake to seturn, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications?

The University of London Question.

THE Convocation of the University of London has, by a large majority, thrown out the scheme for the reconstitution of the University proposed by the Senate. Even those who had little

University proposed by the Sanate. Even those who had httle love for it must feel some sympathy at the furnitation of labours love for the moment the whole question remains in absystace. For the moment the whole question remains in absystace. If modificated to think that it may be useful to discuss, in the interval which must clapse before any further step is taken, some of the fundamental questions which seem to me to underlie the

of the fundamental questions which seem to me to underlie the solution of the problem, and have never, as it seems to me, been groperly considered.

Od'shich a subject one might easily write a great deal. For the sake of brevity I shall therefore attempt to sum up what I have to fix under separate heads.

The Examination System,

One factor in the present situation is undoubtedly the growing dissatisfaction of many distinguished teachers with the examin

tion system as applied to University education. And as the University of London at present does nothing but examine, it is obvious that the question lies at the root of any padgment that move that the custom of the state of th experience, and to teach the conventional and commonplace.

I am free to admit that there is a certain element of truth in what Prof Lankester say. But having had, like him, a good deal of experience both of examining and of being examined, I area of experience out of examining and of being examined, I am disposed to think the picture somewhat over-coloured. No doubt the University of London in the past has exalted examination into a sort of idol. But as regards the superior degrees in science and medicine, at any rate, examination is now practically dispensed with, and the lest of competence is the performance of some kind of original investigation. For the inferior degrees, as far as I am aware, the examina-

For the inferior degrees, as far as I am aware, the examina-tion system in more or less presentible subjects obtain every-where in the three lengthons. For my part, I think the system may be defended, and upon the same lines as those on which the many better than the system of the state of the For he says, and I think rightly, that such an examination 'may be regarded as a means of criticing and testing the performance not merely of the schoolboys but of the school-mancer." Now an University desicning as curried on in this masters." Now in University education, as carried on in this country, I can only see a prolongation of school education, with methods and a moral discipline modified to suit the more admemory and a norm discipline meaned to suff the diore advanced age of the pupils. And the inferior degree (I am not speaking, of course, of professional subjects) is, in my view, nothing more than the corresponding "leaving examination" It is a test of whether teaching has been faithfully done and learning diligently pursued

I am quite ready to admit that impending examinations are more or less irksome both to teachers and taught, but I am not convinced that that discipline is in itself an evil. It is not undesirable that some restraint should be put on the possible vagaries of the one and the very probable desultoriness of the vagants of the one and the very promote destitoriness of the other. It is necessary in entering upon the study of a subject to go over its fundamental groundwork in a methodical manner. To many teachers and to many pupils this is not a little dull. It is easy and it is pleasant to dwell at some length on attractive. parts of a subject and to skim superficially over others There are probably few persons who, looking back upon their own student days, will not admit the truth of this The fact is that student days, with not admit the trust of the letter is grammar; and the majority of young people require some degree of compulsion to make them do it. It may be likeome at the time, but the advantage is life-long. I know, speaking from my own experience, that the compulsion of schedules which is so odious to Prof Lankester has made me devote my energies to the to Prof. Lankeater has 'made me devote my energies to the mastery of the rudiments at any rate of many subjects which I should certainly have carefully avoided if I had not been commercially avoided in the carefully avoided in the carefully avoided in the lands of competent examiners. But then I agree with Prof. Lankeiter that the examiners must know their business, and must not be either ill-informed or pedantic. No one, I have, earning that the kind of men that the University of London enhants in its service as examiners are open to the charge of being either.

If these views are correct, and I believe in the main they are, then the evil consists not in the examination system as the inthen the evil consists not in the examination system as the in-centive to the orderly performance of a curriculum, but in standing an experience of the control of the control of the which the custed world statches to acidemic achievement. "A man refers throughout his life to the fact that he obtained a first-class is a sort of perpectual estimatiat." Of corne, in so first-class is a sort of perpectual estimational. "Of corne, in so study in a means, not an end , it is a sort of appreculocably to a study in a means, not an end , it is a sort of appreculocably to a subject. The situent learns it technique, its larguage, and something of its literature. If he has done this extractly and well, his Driversury will applied him, will call him in accidental

NO. 1125, VOL. 447 '

language "a good boy." But when the congrutation of inringuish has subsoited, the real question arise, what will be dowith the tools he has learn to use? Here, I think, University work catters upon a new phase, and one, it seems to me, too little regarded—I mean port graduate study. To control this in any measure by means of cummation seems to me in the highest investigation, at any rate for its doctorate of scenee, the qualification for that degree, the University of Landon has taken a step in advance of many of the older Universities towards destroying the control of the contr

A Teaching University.

I have always found it not a little difficult to understand what those people exactly mean who to retransuisty demand at eaching University for London. What Frof Lankester means, there is the control of the property of the control of the control

Froit. Lankester adopts the wave of Fichle, who says "that property and the property of the pr

While I cannot help thinking that those who advocate the creation of a so called teaching University in London, have got hold of an idea which they have only imperfectly assimilated, it is still worth while to examine some of the ways in which it might be realized.

In with a readjourner and the second of the country of the country

NO. 1125, VOL. 44

personal contact he can have with his pupils, till at last he has to rely for any infense at all on the atimulus of lecture-room oratory. As Mrs., Garrett-Anderson, has, it seems to me, correctly pointed out in the Thurst, three as very little really to the said in favour of anything like a great central teaching institution for such a city as London.

for such a city as Loudon. The other alternative Incombine University and King's The other alternative Incombine University and King's The other alternative Incombine University and the regarded sea in any way, a statement his proposed with the season of the university of of the university

Furthermore, it is quite a mutake to suppose that unless the extenting University at abulhed, it will be possible for a younger one to caspe its influence. Notwithstanding the establishment of the Victoria University, it is still found necessary, and at the request of Ovens College, to hold the examinations of the University of London in Manchester Consequently, the professor of Ovens College have to adapt their teaching to a double curriculum. If the proposed University of Westimuster and the College of the Co

Expansion of Existing University

It may be taken as quite certain that the existing University of London is too well rooted in the eateen of the community to be got rid of Nor, with this own consent, will it restlyly submit to be mutilated or themembered. And its prise and confidence can brailly be denied that it has accomplished a great work it may be considered to the control of acceleration. This need not be wondered at, seeing that it has always unceredint in entiting in its service the most accomplished and considered to the control of acceleration. It extraordinates the confidence of the co

Instead of typing to dramats and currial the welfathous of an Instead of typing to dramats and currial the welfathous of an Instead of typing to dramats and currial the welfathous of public particular, and the profession of the property of the profession of the provided of the provided to the provided

I will briefly indicate the by no means drastic changes by which this might be gradually provided for.

Organization of the Faculties

I am systl personally impressed with the conviction that the first several personally impressed with the conviction that the first several personal properties of the first several personal per

felt that this is a great evil. Examination is an art, and it is a progressive art. To minimize its possible harmfulness it should keep touch with the teaching. And it must be admitted that keep touch with the teaching. And it must be affinited that the system which now obtains at the University of London does not make this always easy. The Senate is hard to move and slow to act. This would not be so if those who had the right to move it possessed the momentum which would be derived from a more obvious authority. In fact this teacher, to traction arises from a natural Ulmdity. The Senate is too largely composed of persons who have no direct touch with actual

The momentum to which I have referred above would con with all needful force from the faculties if they were organized an a comprehensive way to include every competent authority in academic education in London. I will not stop to discuss the precise machinery by which this should be brought about It seems to me that it would be probably sufficient if the Senate seems to me that it would be probably sufficient if the Senate were to have power to admit to the facultuse the teachers of all institutions of academic rank which supplied it with candidates. To these should be added the past and present examiners, a certain number of non graduates conspicuous for their distinction in the subjects with which the faculty was occupied, and a proper proportion of members of Convocation

Such a body would occupy itself with any and every subject relating to academic education. Its resolutions would embody the deliberate conviction of iastructed and competent persons, and would afford the Senate a solid basis for administrative and would afford the Senate a solid basis for administrative procedure. I need hardly say that the faculties—if they took, as I doubt not they would do, a just view of their functions—would look to the advance of academic interests as whole; they would not seek the sole advantage of the central University, but would which and work for the interests of the collegate institutions they represented—whether in London or the provinces—as well.

Boards of Studies

Delegations from the faculties should be intrusted with the duty of watching the examination work and advising the Senate thereupon. This they would do in two ways (1) they would thereupon. This they would do in two ways (i) they would consider from time to time all alterations necessary in the schedules to as to keep the examinations as closely as possible in did to the control of the contro rejections

Reform of the Senate.

I think it is generally admitted that the time has come when some change in the constitution of the Senate is advisable. At present it is an assembly of notables appointed for life. Many of them never attend, and some, appointed apparently on purely ot them never attend, and some, appointed apparently on purely oplicited grounds—and these are not always the least competent —never perhaps have attended. On the whole, the Seminor though Individually seminent, is, it must be confessed, ill informed on educational mattern. As I have already binted, it is a place to consequence to be somewhat tund and irresolute when it ought to act with decision, it is equally api, I am afraid, to act with the control of the control of moving precipilizary when it ultimately realizes the necessary of moving at all.

The Senate must, however, remain the supreme governing body with whom the final decision must always remain in matters of importance. This being so, it seems not too much mauters on importance
Into Design 80, it seems not too much to ask that it should be an efficiently constituted body, and that the members should attend to their duties. Tenure of office for life it would seem desirable to abolish, and prolonged absence from attendance, say for a year, should type factor vacate a seat. As for the Crown nominees, who are in great part statemen of high rank, it would be on obvious grounds unwise to dispense with them, if they took, as many of them do, sufficient interest in the work to attend with some regularity. Where the Senate in the work to attend with some regularity. Where the Senate needs strengthening is in experts in academic education, and it appears to me that the faculties, if constituted as above, might be intrusted with the duty of selecting these members of the Senate from their own ranks On the whole, it might be convenient to constitute the Senate something on the lines of the Heb-domadal Council at Oxford, a third to be appointed by the Crown, a third to be appointed by the faculties, and a third by Convocation.

NO. 1125, VOL. 44]

Higher Teaching.

There is still, however, one direction in which the University of London might even more closely associate itself with actual This was pointed out in 1872 by the late Registrar, Dr. Carpenier, in his evidence before the Royal Commission on Scientific Instruction. He said (Minutes of Evidence, 10,925), "I think it very important that the State should provide for the "I think it very important that the State should provide for the carrying on of those higher researches, and that higher teaching, which are not provided for in any shape at present." Again (10,926), "I think that a body like the University of London (16,920). "I think that a body like the University of London inglit very advantageously be empowered to take up such higher and more special teaching. At present the University of London has nothing to do with teaching The principle of the University is to recognize existing institutions." I do not think that it would be at all the function of the University to interfere that it would be at all the function of the University to interfere or compete in any way with the institutions which it recognites But I should myself be very glad to see the University and the properties of the properties affiliated to it." The copy of this higher teaching was brought out more clearly in a subsequent part of Dr. Carpenter's evidence in answer to a question of Prof. Henry Smith, (0.953) He anded, "The Senate might at one future time endeavour, might they not, to have such lectures given in connection with the University of Lunglon as are now greef in

connection with the University of Lendon as are now given in the Collège de France's—Ven, more of that character, why provided the Collège de France's—Ven, more of the character, why provided the Collège de Co lectual life of London

It is just possible that it may be objected that the proposal to have a superior professoriate attached to the University is in some degree a slight on the Colleges and their teachers. And it some edgree is upon to the concepts and men leachers. Find in may be urged that, if there were any demand for post; graduate teaching, the Colleges are quite competent to provide it in may be so, but in practice I do not believe it feasible. The working day is inelastic, and from what I myself know of the labour involved in what may be called systematic graduation. sahour involved in what may be caused systematic graduation courses, I do not believe that the same man can superadd hhe higher work as well. Besides, to be of any value, it must not be formal and perfunctory, the essence of the higher teaching is that it should reflect the research to which the occupant of each chair should be able to devote the whole of his time

each char should be able to devote the whote of his time de as, at I do not think that such professorships will be founded. For his and other reasons I about gladly see the University cease to be a quast-Ooverment ministrieu, and launch out on its own resources. It seems almost incredible, but it is a fact, that at the present time not the "slightest alteration can be made in a schedule without the approval of the Home Office, or the slightest alteration in the amount of prizes without that of the signess atteration in the amount of prizes without that of Treasury. There is no inducement now to the public to pro-vide endowments, because, as the University nearly pays its way any public been faction would only tend to create a surplus, which would have to be paid over to the Exchequer. But I can hardly doubt that if the University were cut admit from the State it doubt that if the University were cut admit from the State it would receive endowments which would enable it from time to time to found useful and important chairs. These would form not an unwelcome addition to the too few prizes accessible to those who devote themselves to learning for its own sake.

those who devote themselves to learning for its own take.

I had it in my mind to any a few words about the very complicated but independent problem which medical University to the problem which medical University to an indicarble length, and the subject is perhaps of limited interest to the readers of NATUKE But I may say that I believe that the organization of a strong medical faculty would bring about the solution of all existing difficulties.

ROWAL Gardonn Key, May 18, W. T. Hithstron DYER.

Royal Gardens, Kew, May 18.

A NOTE in the last issue of NATURE (p. 39) seems to assume that the present University of London is nothing but an Imperial Examining Board that has got wrongly named, and stands in the

way of London possessing the educational advantages of a German University town
I venture to offer some facts and considerations which may

nodify this view, and perhaps aid in forming a juster conception of the real nature of the University question than is commonly entertoined

Much more important matters are involved in the question than the maintenance or extension of existing institutions, though these are quite legitimate subjects of discussion and defrozen the columns of NATURE it is only upon the broad ground of the advancement of science and learning that the

ground of the advancement of science and vacating time are question can be dealt with The epithet "Imperial" is intended to imply some unitiness on the part of the present University for other than "Imperial" functions, whatever these may be. But the University has not, and never has had, the lesst claim to any such title. It has never at any time held columnal examinations of its own motion It has never at any time held any colonial examinations whatat this never at any time next any Cotonia examinations what-ever in the faculty of science, or in the faculty of medicine, or for honours in any faculty, or for any of the higher degrees What examinations it holds in any colony are held only at the request of the Governor of the colony, transmitted through the Colonial Office, and are practically confined to matriculation and the intermediate examination in arts Occasionally, but very rarely, an examination in laws or for the Bachelor of Arts is held in some colony. In 1850, 16 cendidates materialised in the colonies, and 5 pussed the intermediate examination in aits out of a total of some 5000 candivites. Not a single degree examination was beld in any col only. In fact, these colonial examinations, which, few as they are, pearly disminish in sumber, and the colony of the colony of the colony of the colony of Mauritius, but were extended and have been maintained about 1864, at the requised of the colony of Mauritius, but were extended and have been maintained chelly to facilitate the swarf of the ecolonistic at the colony of the colon of the colony of the colony of the colon of the colony of the colon of the colony of the colon of the colony of th held in some colony. In 1860, 16 candidates matriculated in the

gene mouthly choint roun minuma data content regional and appears are now drawn from an area harmy London for its centre with a radius of not more than 100 mile. The probable establishment, at no very remote period, of provincial Universities will practically give a still more exclusive sense to the nance University give a still more exclusive sense to the nance University give a still more exclusive sense to the nance University in and for London. The creation of which is constantly pair forward as the principal educational need of the metropolis. Is the proposed University to the "for" London Confond, or that of Editable the New York of the Confordon of the Statistical Con

intended to impose focal limitations which no University his every ext imposed upon itself.

The expression "teaching University," too, stands in need of acated definition. The University of Edinburgh is a teaching Carteria of the Carteri University of London would be the examination of collegiate University of London would be the examination of collegates candidates and those only by their teachers in alleged conformity with the principle that examination should follow teaching. But it may be admirted that teaching ought to be adapted to examination, or examination to teaching, without admired that teachers settling the manufacture of the state o mixing any advantage in the system of reachers setting the examination of their own students, collegiate or not. The combined teacher examiner system is not wholly trusted by its supporters. At the older Universities the examiners are by no

means usually the teachers of the candidates, at the Victora University one of the examiners is always an "external Section Annotation and the section of the candidate and the section and th London?

Further, is it not misleading to characterize the University of Further, is it not misleating to characterize the university of London as a mere Examining Bard? Of the three fanctions of such a teaching University as that of Edinburgh, it performs two It directs teaching by yillabuses and regulations (pre-pared with extreme care, and not without ample reference to the best authorities on all matters of special knowledge), and it tests teaching by absolutely impartial and disinterested examina-tions, but it does not-without space, funds, and appliances it tions, but it does not—without space, funds, and appliances it could not—pretend to teach. Nothing, however, in its nature or essence forhids its development, alone or in union or conjunction with other institution, into what would be an ideal University of the non residential order, neither coercive nor exclusive—one that should offer proper University instruction. to all comers, and, at the same time, confer degrees upon open examinations independently (save for obvious reasons in relation

examinations inageneously (see for obvious reasons in reasons to medical degrees) of place or mode of instruction the part the existing University of London has played in the advancement of learning may be indicated by the fact men-tioned by the Vice-Chancellor in his Presentation speech, that during the last thirty years—that its, since its examination, were suring, ne fast turry pears—that it, since its examinations were thrown open—the number of degrees conferred by the University has increased tenfold. This, however, is only one of the ways in which its influence is shown, the great advance in scientific education the last fifty years have witnessed is almost wholly due to the stimulus and example of the University of But the subject is too large a one to be dealt with on the present occasion, and indeed, from its nature, scarcely lends itself to treatment capable of doing full justice to the University. The work of a University should not be confined to the edu-

The work of a University should not be confined to the edu-cation of graduates. Hs crowning function is the exposition and illustration of the higher learning along the whole line of dwance. Such is the task so admirably accomplished by the Surhonne and the Collège de France, and to the world of science and learning in London the University of London is peculiarly well adapted, by its independence and impartiality, to render similar services Some years ago an attempt was made to work similar services—Some years ago an alternit was mane to work as cheme having this end in view, but, in deference to reason, that no longer exist, it was found necessary to abandon its further provecution. Its resumption has now become, or may shortly become, simply a question of means, and the time is at hand when a strong effort ought to be made to afford scholars. and men of science in London some of the advantages their and men of science in London Paris.
brethren have so long enjoyed in Paris.
F, Victor Dickins

Co-adaptation

WRITTEN letters remain. It is for anyone who may read this correspondence through at one time to judge on which side lie the "valid" distinctions, and on which the "invalid" con-fusions—not to mention comparisons in respect of "verbiage" or fauson--not to mention companions; in respect of "rerbinge" or more personaismes. But I am obliged to write one more to inside, for the fourth time, that my agreement with Prof. Mid-of co adaptation," but only to stating that co adaptation must be proved not to exist, if "Mr. Spencer's argument" is to be logically met. And if, as Prof. Meddol now say, any vach statement to be found in his "review of Mr. Pancoc's book." (which, A repeat, mercy reproduces "Ant. Valence's argument as to the decommission of adaptations, without remarking that this has no relevancy to the argument from co-adaptation), at must be in that "language of their own" which the neo-Darwinians find "to be intelligible among themselves."

Christ Cherch, Oxford, May 15. GROKEN J. ROMANES.

A priori Reasoning.

I SEEM to have failed to make my contention clear to Mr. Cockerell, and will try once more. What I maintain is this:

that it is unscentific—unphilosophical—to gate an hypothesis or formulate a theory, and much more as to make a categorical or formulate a theory, and much more as to make a categorical verification at tempted. Thus, Mr. Cockerell task the question, "Why is it that plants growing on exposed sea-thores have a tendency to the upon the ground or otherwise is enade the tendency to the upon the ground or otherwise the sender labe too bring forward that the purpose of lying down as to evide the volence of the winds? So far, it is nothing more than has private opision—an a preser assumption. It is true that he adds a reason, but it is an demay more than has private opision—and preserva assumption. It is true that he adds a reason, but it is an demay more than its order to the sort consolences, and not from nature . "When a plant is growing among others, it has to compete with them in raising itself into conspicuoushas to compete with them in raising itself into conspicuous-ness." But do not dwarf plants ever compete? My experience of the South Downs, where plants are for the most part con-siderably dwarfed, is that the struggle between them is a severe one. Yet their flowers and foliage are fully exposed. severe one ret their nowers and tollings are unit exposed to sunlight and insects, as well as to severe gales of wind. Mr. Cockerell also appears to forget that what is true for one plant is true for another, and each must try to overtop all the others.

I would venture to warm our younger naturalists most ear-nestly against this facilis descensis of a priors reasoning with-out facts or verification. It has been the baine of metaphysics; and when a scientific man like Dr. Weismann puts forth, in the name of science, most deplorable illustrations of it in his late attempt to apply his theory to plants, it is time that some one should venture to protest

one should wenture to protest
In reply to his request, it would refer Mr. Cockerell to M.
Verlot's pamphlet "Sur is Production et la Fixation des
Varides," in which he describes his method of creating and
fixing dwarf plants by sowing seed late in the season. Also to
M. Rosjou's experiments in electing the smallest seeds of
plants (Fourn d'Hist Not de Bordeaux et du Sud-Ouest,
1854). Mr. Mohab also raused dwarf Hodedendons by using pollen from the smallest stamens Want of space forbids me adding more on the subsect. Gronge Henslow. adding more on the subject.

The Natural Selection of Indian Corn,

In a former letter I had occasion to mention that Zea mais varies in its period of maturing, and that at certain altitudes and latitudes, only some of the varieties (s c. the early maturing) are able to mature at all, the rest being absolutely eliminated by natural selection in a single generation. A few days ago I received, through the kindness of Mr James Fletcher, the new (1891) Report on Experimental Farms for 1890, published by the Canadian Government, in which are numerous statistics of experimental planting in different parts of the Dominion. On p. 296, Mr. T. A. Sharpe gives an account of the result of planting twenty-nine different varieties of Indian corn at Agassiz, British Columbia, which perhaps deserves notice, as illustrating the above-mentioned facts in a particularly clear way. Of the varieties planted (all exposed to the same kind of environment), the majority did not form any ears at ail. Some formed very small ears, and others reached various stages of maturity, but only a very few actually matured.

For example, I will quote some of them -

No. 1. Moore's Early Concord, corn matured, one of the

best. 3 Early Adams, corn matured to glaring stage.
6. Mitchell's Extra Early White Flint, produced some

matured ears.

No. 11. Marblehead Sugar, matured corn, ears very small.
No. 12. Narraganset, aweet, corn did not fill to tips of cob.
No. 14. Chester Co. Mammoth, no corn formed
No. 21. Golden Dent, no ears formed.

T. D. A COCKERELL. 3 Fairfax Road, Bedford Park, Chiswick, W., May 10.

The Soaring of Birds

IT seems a great paty that the simpler form of this questionwherein birds soaring steadily rise, in a gentle breeze, over a large plain—is needlessly complicated by the flight of sea birds

over waves
we shall get the solution best by taking the former and less
ownplicated case, wherein the pelicans, adjutants, cyrus, vultures, &c., stody see, by soaring alone, to great heights, under
conditions where up-rushes of air are quite out of the question.

Upper Asam is a dead level, aoue 60 miles wide by 200 long, and over this area, wherein these birds rise by soaring alone, the alt-offit is almost nuvariably from north-north-east, or else south west, and at about 5 to 10 miles an hour. They do not seem to rise in a dead calin, nor yet in stormy weather, and I take it the desideratum is a slow art-offit, or gentle standy.

breeze. That there are no up-rushes of air, I have fairly good proof in the small tufts of cotton, from the Bombys: melabaricum, which cross the field of my telescope when examining the Noga Hills at 10 to 20 or 30 miles; these are always beautifully horizontal at elevations from 200 to 2000 feet, coming from the plains and

hills north-east of us. So that out here there is no complication of the case by verso that out neer there is no complication of the case of year tical movements of the air, as at sea. The question is not how large birds sustain themselves (without flapping their wings) in a wind, when there are rising and failing and sixtato "different velocities"; but how large birds like the cyrus, adjutant, pel-can, and wilture can rise from 300 to 3000 feet, in a **idedy*

breeze, without flapping their wings
It is not mere floiation, they have to raise 20 or 30 pounds
some 2000 feet, in addition to what the albatross does.

Surely this is the major question, at once simpler to see, and more difficult to answer

In NATURE (vol. xxiii p. 10) I drew attention to this, and sent a small diagram, to show how I thought it was done. I have frequently observed the phenomena since, and see no reason to modify my view

reason to modify my views.

Firstly, these large brids on me sear in a dead calm, or a
Firstly, these large brids.

They prefer a stansfty recommendation of the control of the control

Secondly, they rise from the ground, by flaspung the wings, and continue this till they are 100 or 200 feet up, and the begint to soar, in right or left hand spirals, 100 or 200 yards across, At each lag help rise 100 or 200 feet, and make as many yards leeway, drifting slowly routh the wind, and continue thus to rise until out of sight above.

With a good telescope a bird can be easily followed after a little practice, and the only motion which can be seen is slight and occasional movement of the tail, in sleering.

The legs (of the waders) are extended at full length behind, the neck thrown on the back, and beak projecting over the

feathers are always well separated in different planes.

evidently under great strain evidently under great strain.

The lifting power is evidently applied to them mainly, and the plane of the outspread wings is not horizontal, but forms part of an obtuse, inverted cone, as though a little centrifugal force was implicated.

The speed of the bird is always greater than the breeze, and the resistance is unequal on opposite sides of the loop of the spiral; least when it travels with the breeze, and greatest when on the opposite half, meeting it

on the opposite mai, meeting it.
It seems to me the solution is that, when going with the wind,
the bird gathers momentum by going down a slight incline, and
when it turns and meets the breeze, the extra momentum is
used in lifting the bird and extrying it over a Moritr course.
Thus it sterts the next lap at a MgMiD higher level, but some 20

Thus it stars the next lap at a n/ga/h/ higher level, but some so yeard to leawers. Variation of the speed of the wind at different levels is here quite out of the question; the bard, too, keeps to level in here quite out of the question; the bard, too, keeps to level in the profit profit

ON SOME POINTS IN THE EARLY HISTORY OF ASTRONOMY!

HI.

WE now come to the important point for our present inquiry—the direction in which the temple is built, or, technically, its orientation. Confining ourselves for the moment to Karnak, is there any meaning in the direction of that line, some 500 yards long, which is obviously the main feature of the building, and to which all parts are accessories?

How can we instrumentally determine this? I have the necessary apparatus here, and the question may be answered in a few minutes, we have simply to determine either the aimuth or the amplitude (and as we have seen one of these gives the other) of the point of the hormon towards which this long line is directed

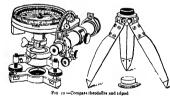

The azimuth compass is an instrument familiar to most of you. It consists of a magnetic needle fastened

Fig. 17 —Azimuth compass. sv, direction pointer, 11, sun shade (for observations of sun), 1, reading prior, A B, graduated card with attached

to a card carrying a circle divided into 360°, which can be conveniently read by a prism when the instrument is turned toward any definite direction marked by a vertical

A theodolite armed with a delicately hung magnetic needle which can be rotated on a vertical axis will do equally well, it has first of all to be levelled, there is a little telescope with which we can see along the line

When we wish, for instance, to observe the amplitude of a temple, the theodolite is set up on its triped in such a position that we can look along the temple wall or line of columns, &c., by means of the telescope. We then get a magnetic reading of the direction, after having unchamped the compass; the compass showing the angle made between the line and the magnetic north (or south), as in the azimuth compass.

Having made such an observation as that I have de-

NO. 1125, VOL. 44]

scribed, the next thing we have to do is to determine astronomically the real north, which is the only thing of value. There are two ways of getting this astronomical bearing or azimuth

It is sad to think how much time has been lost in the investigation of a great many of these questions, for the reason that the observations were made only with reference to the magnetic north, which is vastly different at different places, and is always varying; few indeed have timed to get at the astronomical conditions of the problem. Had this been done either by the French or Prussian Commissions to which I have referred, it is perfectly certain that years ago the solitical orientation of Karnak and other temples which I shall have to demonstrate to

you would have been long known to all scholars If the magnetic varation has been determined for the region we may use a map. Such a map as that shown in Fig 13 gives us the lines along which in the Bristh lists the compass variation west of north reaches certain values would along a line extending from a little to the west of Cairo to the second cataract would have had a variation of 12° to the west, in 1844 of 8° to the west; and at the present time the variation is such that observations made along the same part of the Nite valley will have a variation closely approximating 5° to the west. By mean such such a map it is guite possible to get approximately the such an approximation of the such such such that the such such such which can be observed in the present day.

If we are not fortunate enough to possess such a map, the theodolite will enable us to observe the direction in which the sun culminates at noon. This gives us the south point astronomically From observations of the pole star at night, the astronomical north can be determined. From either of these observations the magnetic variation is obtained without any difficulty variation is obtained without any difficulty.

This being penised about the melhod, we next come the results. The melhot was the results of the plants of the control of the control of the plants of the control of the control of the plants of the plants is 50° N; of W, which we learn from the table already given is precisely the amplitude of the place of sunset at the summer solution. The amplitude of the point to which the axis of the small temple points is 26° S; of E, exactly the position of sunnies at the winter solution.

There is more evidence of this kind Abydos, one of the oldest temples in Egypt, built, according to tradition, by the servants of Hor, is now, its true, a heap of ruins, the brick walls best showing its direction; but it is possible to the showing its direction; but it is possible to the solid properties of the prope

At Alydos, then, as at Karnak, we get exactly, within a degree, the amplitude shown in the tables for the sun in the Nile valley at sunset at the summer solstice. So that the Egyptians who were employed in building those temples must have known exactly what they were going to do, and what they did was to-build a temple such that the sun at setting should, at the summer solstice, pour its light along the axis of the temple I Maspéro and the great

authorities in Egyptian archeology are right-mainty, that the Allydos temple was founded before 4,000 nC — and if we can depend upon the French figures, we are driven to the conclusion that we have in this temple a building which was orientated to the solitutial sunset place in the valley of the Nile. The Nile valley holds other solar temples besides those we have named, but it is best to fully study Karnaki; instead of being a mere beap, the orientation of which is obtainable only by the general lie of the remains, thus temple is still in such

preservation that the Germans, in the year 1844 could give us an infinite number of details about 14, and locate the position of the innumerable courts. Its orientation to the iolatice we can claim as an early astronomical observation. So its quite fair to say that, many thousand observation. So its quite fair to say that, many thousand it events, the Egyptians were perfectly exam got at all events, the Egyptians were perfectly fully with the yearly path of the sun.
But so far we have only dealt with solutions: Did

But so far we have only dealt with solutions. Did the Egyptians know anything about the equinoses? Certainly Nothing is more remarkable than to go from the description and the plans of such temples as we have seen at Abydos and Karnak to regions where, apparently, the thought is totally and completely different, such as we find on the Fyramid Plains at Chitek, the orientation of the control of the control of the control openion, that these structures are just as true to the sun-rising at the equinoses as the temples at Abydos and Karnak were to the sun-rising and setting at the solutions,

Fig. 13 -Map of British Isles showing the magnetic variation 1

and the Sphinx was merely a mysterious nondescript sort of thing which was there watching for the rising of the sun at an equinox, as the Colossi of the plain at Thebes were watching for the rising of the sun at the winter solstice. The observations which have been made in Babylonia

The observations which have been made in Babylonia in the signature of the

For Figs 11-73 I am indebted to the kindness of Mr Stanley, Great Turnstile, Lincoln's Inn Fields.

NO. 1125, VOL. 44]

seeing the rising of the sun on the day of an equinox, possibly at the time which we now call Easter.

possibly at the time which we now Call Easter.
All the doors being opened, the sunlight would penetrate over the high altar, where the sacrifices were offered, into the very Holy of Holies, which we may remember was only entered by the High Priest once a year.

Have we any other evidence except the evidence and forded by temples? Yes. I thus been stated that we have no temple evidence from China, but there is a good deal of written evidence, and there is no doubt that in China the solstices and the equinoxes were perfectly well known 1100 years is C. Was it difficult to obtain this knowledge? Did it indicate that the people were great astronomer? Noting of the Guiding Order is so uses, as to determine a Noting of the Guiding Order is so uses, as to determine a

We know from the Egyptian tombs that their stock-intrade, so far as building went, was very considerable, they had squares, they had plumb-lines, they had scales, and all that sort of thing just as we have Suppose an

Il that sort of thing just as we have Suppose an Egyptian wished to determine the time of an equinox. He would first of all make a platform quite flat, he could do that by means of the square pretty sharp edges (and such rulers are found in their tombly, and in the morning of any day he would direct this ruler to the position of the sun when it is rising and he would draw a line; he would do the same thing in the evening when the sunset, he would breat the angle made by these two lines, and it would give him naturally the north and south points, and a right angle to those would give him the cast and west. So that from observant of the country of the country

the equies another way of doing it. Take a vertical rod. Suppose that the sun is rising, let the rod throw a shadow, mark the position of the shadow at sunset we again note where the shadow fails. If the sun rises exactly in the east and sets exactly in the east, those two shadows will be continuous and we shall have made an observation at the absolute equinox. But suppose of the shadows equally long before and after noon will be an east and west line.

It is true that there may be a slight error unless we are very careful about the time of the year at which we make the observations, because when the sun is exactly east or west at the time of rising or setting it is moving most rapidly. So it is better to make the above observations of the sun next the solutions than the equinose, because the countries of the sun face of the sun

Such a rod as this, which I may state is sometimes called a genome, may be used with another object in view. we may observe the length of the shadow cast by the sun when it is lowest at the winter solstice, and when it is highest; at these two positions of the sun obviously the lengths of the shadow at horn will be different. When we have the shadow into more than the shadow will be least, when the sun it more removed from the vertical the shadow will be longer.

The day on which the shortest shadow is thrown at noon will define the summer solstice; when the shadow is

longest we shall have the winter solstice.

This in fact was the method adopted by the Chinese to determine the solstices, and from it very early they found a value of the obliquity of the ecliptic.

It may be said that it is only a statement, and that the record has been falsified; some years ago anyone who was driven by facts to come to the conclusion that any very considerable antiquity was possible in these observa-tions met with very great difficulty. But the shortest and the longest shadows recorded (700 years B.C.) do not really represent the true lengths according to recent knowledge If anyone had forged these observations he would state such lengths as people would find to-day or to-morro but the lengths given were different from those which would be made to-day Laplace, who gave considerable attention to this matter, determined what the real obliquity was at that time, and proved that the record does represent an later years.

The solstices and the equinoxes were therefore in all probability thoroughly known to the Egyptians 4000 years BC, perhaps even 5000 We are then justified in considering that the temples at Abydos and at Karnak are really solar temples The Egyptians marked the solstices and the equinoxes not only by their temples but in their calendars, which these temples enabled them to construct The Chinese had also this knowledge, but we have no

information that they possessed it at so early a date.
In the next place, then, I propose to make a special study of the temples at Karnak, because they are those which are most capable of minute investigation. I do this in order to see whether any other indications can be obtained of any higher knowledge possessed by the Egyptians of

those early times.

I must again point out that we deal with the solstices in the case of the temples at Abydos and Karnak, and with the equinoxes in the case of the pyramids, some mounds in Babylonia, and the Temple at Jerusalem Since the labours of the French and Prussian Governments who have given such full records of Karnak, a memoir on the temples has been published by Mariette, which gives us not only plans, but precious information relating to the periods at which, and the kings by whom, the various parts of the temples were constructed or modified

We may begin by the general plan of Thebes find there a perfect nest of temples No doubt those which are still traceable form only a very small portion of those which once existed, but however that may be, I of those which once existed, but however that may be, i have now only to call attention to one or two among them. In the general plan we see indications that on both sides of the Nile there were temples pointing to those special amplitudes which I have before referred to What we have first to do is to refer to the solstitial temples, those which point to 26° N or S. of E or W, in which we have undoubtedly indications of the early attempts to observe, or to worship, the sun at sun-rising and at sun-setting, at the critical times—the solstitial times of the year.

The first point that I wish to make is that these temples-whatever views may be entertained with regard to their worship or the ceremonial in them-were undoubtedly constructed among other reasons for the purpose of obtaining an exact observation of the precise time of the solution. The priests having this power at their disposal, would not be likely to neglect it, for they ruled by knowledge. The temples were, then, astronomical observationes, and the first observationes

that we know of in the world

If we consider them as horizontal telescopes used for the purpose I have suggested, we at once understand the long axis, and the series of gradually narrowing diaphragms, for, the longer the beam of light used, the greater is the accuracy that can be obtained.

It is worthy of note that the direction of the temple at Karnak is quite independent of the locality, it has nothing to do with the presentation of the temple to the

although they are parallel to each other, their presentation to the river in the different localities is very various What then was the real use of these pylons and these diaphragms? It was to keep all stray light out of the carefully roofed and darkened sanctuary; but why was

the sanctuary to be kept in darkness? Independently of ceremonial reasons-there is a good deal to be said under that head-it is quite clear that the darker the sanctuary the more obvious will be the patch of light on the end wall, and the more easily can its posi-tion be located. It was important to do this on the two or three days near the solstice in order to get an idea of the exact time at which the solstice took place. We find that a narrow beam of sunlight coming through a narrow entrance some 500 yards away from the door of the Holy of Holies would, provided the temple were properly orientated to the solstice, and provided the sol-stice occurred at the absolute moment of sunrise or sunset according to which the temple was being utilized, practically flash into the sanctuary and remain there for about a couple of minutes, and then pass away. The flash would be a crescendo and diminuendo, but the whole thing would not last above two minutes or thereabouts, and might be considerably reduced by arrangements of curtains Supposing the solstice did not occur at the precise moment of sunrise or sunset, and provided the Egyptians by any means whatever were able to divide the days and the nights into more or less equal intervals of time, two or three observations of the sun-rising at the solstice on three different mornings, or of the sunset at the solstice on three different evenings, would enable a careful observer to say whether the solstice had occurred at the exact moment of sunrise or at some interval between two successive sunrises, and if the latter, what that interval was

I now come to my next point, which is that here we have the true origin of our present means of measuring time-that our year as we know it was first determined in these Egyptian temples and by the Egyptians We have seen that it did not require any great amount of astronomical knowledge to determine either the inoment of the solstice or the moment of the equinox. I think you will agree with me that the most natural thing to begin with was the observation of the solstice, for the reason that at the solstice you can watch the sun day after day getting more and more north or more and more south until it comes to a standstill. But for the observation of the equinox, of course, the sun is moving most rapidly either north or south, and therefore it would be more difficult to determine in those days the exact moment, so that I have little doubt that what they attempted in the first instance was to mark the absolute moment of the solstice. If that be so, and if Maspéro is right that Abydos was built before Menes, then we know definitely that the Egyptians could and did observe the solstices, and knew what they were doing, 7000 years ago

and knew what they were doing, 7000 years ago Before I say anything more about the use of these temples in determining the year, it is worth while to note how very different the treatment of this subject was in Egypt to what it was in Chaldesa and Babylonia and among the Jews. We do of course in. the Egyptian inscriptions read of the moon, but in Chaldea it would seem that the moon was the chief thing worshipped, and it was thus naturally the chief means used for measuring time, and, as far of course as months were concerned, this time, and, as far of course as months were concerned, the was quite right. In Chaldrea, where they were not dependent upon the rising of the Nile, and where much desert travel had to be undertaken at night, the moon and the month were the points considered, and the sun was hardly regarded at all from that point of view An in-Nile or to any other particular part of the landscape, and that point, I think, is absolutely settled by the conjoint, I think, is absolutely settled by the conjoint, I think is a basolutely settled by the conjoint, I think is a basolutely settled by the conjoint, I think is a basolutely settled by the conjoint, I think is a basolutely settled by the conjoint, I think is a basolutely settled by the conjoint, I think is a basolutely settled by the conjoint is the same category.

Thus, for instance, in Egypt the sun being used, the unit of time was a year; but in Chaldea the unit of time was a month, for the reason that the standard of time was the moon. So that when people began speaking about periods of time it was quite easy for one nation to conceive that of time it was quite easy for one nation to conceive that a period of time was a year when really it was a month, and vice versal. It has been suggested that the years of Methuselah and other perions who are stated to have lived a comiderable number of years were not solar years but lunar years—that is, propelly, lunar months. This is reasonable, since if we drived the numbers by 12 we find that they come out very much the same length as lives

are in the present day The Egyptians, taking the sun as their measurer of time, began very early with a year of 360 days. For some reason or other they divided these 360 days into months, probably with some lunar connection, so that they had 12 months of 30 days Now, we know that that is not the true length of the year, and it is clear that any is not the true length of the year, and it is creat that any nation which uses such a year as that will find its festivals going through the year. Further, such a year as that is absolutely useless for the agriculturist or the gardener, because after a time the same month, to say gardener, occasies after a time the same month, or same nothing of the same day of the month, will not mean reaping-time, will not mean sowing-time, or anything else. So that this 360-day year did not last very long; so long as it lasted, however, they knew that they got the seasons back to months of the same name in a period

of 70 years
This method led to complications, which possibly may have had something to do with the building of these temples. Egypt being exclusively the gift of the Nile, you can quite understand that their earliest calendar would be connected with the Nile, and so one finds it. would be connected with the Nile, and as one most with We and other peoples occupying the zone in the north divide the year into four seasons, the Egyptians divided it, and still divide it, into three they have four months of the flood of the Nile, then they have four months after the Nile has retired, in which they do their sowing, and summer, in which they gather their harvest.

we began, then, with a year of 366 days, and, having 360 days instead of 3654, we had a cycle of 70 years, and during that cycle each day of the year meant something different with regard to the advance of the seasons, and with regard to the work of the agriculturist and the gardener to what it had meant in the preceding year But this state of things did not last long. The 1st of the first month fell at the summer solsting on June 20, and the reason that it fell then was, that the mundation and the reason that it fell then was, that the mundation of the Nilercached Memphis on that day. Whether with the help of the temples or not, they soon got very much mearer, and changed the year of 300 for one of 306 days, which is, roughly, within a quarter of a day of the truth They had still lither 12 months of 30 days, and then they added an extra month of 5 days. With their perfectly orrentated temples they must have soon found that their correlated temples they must have soon found that their festival at the summer solstice-which festival is known all over the world to-day—did not fall precisely on the same day of the new year, because, if 365 days had exactly measured the year, that flash of bright sunlight would have fallen into the sanctuary just as it did 365 days before. But what they must have found was, that days netore. But what they must have a stall on the first day of the month, but on the day following it. They at once faced this, and found out that 365 days did not exactly make a year, but that they had to do with a quarter day in addition. What the Chinese did was this: every fourth year, instead of adding 5 days to their 360, they added 6 days, and in that way they practically brought the calendar right

Theory indicated that retaining the 365-day year, the 1st of the first month would come back to its exact relationship to the mundation of the Nile after a period

of 1460 years, the 1460 years of course depending upon the quarter being added (365 × 4 = 1460). This was known in Egypt to the priests alone. They

would not allow the year of 365 days, called the vague year, to be altered, and so strongly did they feel on this point that every king had to swear when he was crowned that he would not alter the year We can surmise why this was. It gave great power to the priests; they alone could tell on what particular day of what particular month the Nile would rise in each year, because they alone knew in what part of the cycle of 1460 years they were, and in order to get that knowledge they had simply to continue going every year into their Holy of Holies one day in the year as the priests did in Jerusalem, and watch the little patch of bright sunlight coming into the sanctuary. That stice to their year, which was supposed to begin at the solstice, and the exact date of the mundation of the Nile

solstice, and the exact date of the inundation of the Nile could be found by those who could determine observationally the solstice, but by no others. In reading books on Egypt we come across another cycle which is supposed to be a very mysterious one; in fact it is one which, I think, has not yet been sufficiently investigated, and it is very well worth the trouble of anybody who will give the time They begin with a year of twelve months, each of which has thirty days, thus giving 360 days, this was found not to work. They then tried 365 days, but that also would not work, because then tried 3c5 days, but that also would not work, because then the first day of Thoth (their first month) would only indicate the inundation of the Nile one year out of 1460; and then the priests interpolated the other day and got the cycle right, but it was not yet quite right. In the time of Hipparchus 367 3cf did not really represent the

time or ripparchus 305 25 did not really represent the true length of the solar year, instead of 357 28 we must write 305 242992—that is to say, the real length of the year was a little less than 305 days.

Now the length of the year being a little less, of course we should only get the absolute coincidence of the 1st of Thoth with the nundation of the Nile in a longer period. than the 1460 years cycle; and, as a matter of fact, the 1460 years had to be expanded into 1506 to fit the months into the years with this slightly shortened length of the year, so we have a period which is called sothic, of 1460 years, and a period which is called phanix, of 1506

There is a great wealth of interest connected with the uses of the temples from the point of view of worship, but that does not concern us here, except that it is intimately connected with the next part of the subject, for I have next to point out that it necessitated in Egypt, Chaldrea, and elsewhere contemporaneous observations of the stars I therefore now pass from the sun to the stars

I NORMAN LOCKYER.

(To be continued.)

FORESTRY IN NORTH AMERICA

N continuation of the notes under the above heading which appeared in NATURE last January, I wish to refer to a splendid paper recently read by Sir Dietrich Brandis, F R S, to the Natural History Society of Bonn It consists chiefly of a compilation from Dr Mayr's book, "Die Waldungen von Nord America" (Munich, 1890), and from works by Prof. Sargent Bernhard Fernow, the present Chief of Forestry at Washington, and some other authors, as well as from the Agricultural Reports of the United States.

Dr. Mayr is the son of a Bavarian State forest officer, and, after studying forestry and botany at Munich, he was sent, at the expense of the Bayarian Government, to observe in their native forests, at different ages, certain important ¹ "Der Wald in den Vereinigten Staaten von Nord America," von 1)r D Brandis in Bonn, 1891. (Sonder Abdruck aus den Verhandlungen der Naturhistorischen Versun, 47 Jahrg.)

North American forest trees, experimental plantings of which have from time to time been made in Germany After spending seven months on these researches, and ex-tending his tour through Japan, Java, Ceylon, and Northern Hindustan, Dr Mayr returned to Germany in 1888, and ringustan, Dr Mayr returned to Germany in 1888, and was shortly afterwards appointed Professor of Forestry and Forest Botany at the College of Agriculture and Forestry at Tokio in Japan. The present writer had the rorestry at 10kio in Japan. Ine present writer nad the great pleasure of accompanying him in January 1888 for about three weeks through some of the conferous and oak forests of the North-Western Himalayas and the subtropical forests of the lower hills near Dehra.

After leaving Germany a second time for Japan, Dr Mayr had a further opportunity of visiting North America, and thus has twice traversed the length and breadth of the country between the Dominion of Canada

and Mexico

Mayr treats of the demands of the most important North American trees as regards climate and soil, with a summary account of their anatomical structure and of the physical and technical qualities of the most important woods, and his book contains numerous illustrations. He also gives lists of destructive fungi and insects observed

by him on the different species.

Brandis has some criticisms to mete out for a few somewhat rash generalizations made by Mayr These are that evergreen broad-leaved (not comferous) forest requires a higher winter temperature than deciduous forest, and that deciduous forest vegetation is always absent in tropical countries on account of the uniformity of the climate throughout the year Brandis shows clearly, from a comparison with the deciduous forests of teak and other species in India, Burma, and Java, that this statement will not hold wherever there is a prolonged dry season, which renders the trees leafless for a certain period of the year

Another statement of Mayr's controverted by Brandis is that conifers never grow in tropical countries except where the altitude renders the chimate non-tropical, and that in North America they have longer needles, supply times in NOTIO AMERICA they have longer needles, supply heavier timber, and contain the more resin, the nearer they grow to the tropics. The latter statements may be true for Pinus australias, the putch pine of the Southern States of North America, but do not hold good in India, where the Pinus longified of the Humalayas has the where the First imperious of the symmetry many a max the tropical pine (P Merkentri), which however, has the heaviest wood of all the Indian pines, and grows in latitude 17° N, in Tenasserim, at about 600 feet above sea-level, in an absolutely tropical climate

Mayr's statement that oranges will only grow to perfec-tion in a hot dry climate is also not true for India, as tion in a hot dry climate is also not true for India, as oranges of splendid flavour are grown in enormous quantities in the damp lower hills below Cherapunj, in Assam, where the ramy season lasts for eight months, as well as in the dry regions near Delhi, and the comparatively dry country near Nagpur, in the Central Provinces

of India.

Apart from these criticisms and an interesting discussion on the origin of prairies, we find in Brandis's paper a most complete account of the distribution of North American forest trees.

Forest vegetation is much richer in North America than in Europe, containing about 412 species, distributed as follows :

Atlantic region 176 106 Pacific region . Common to both . .. 10 Central region on and surrounding Rocky Moun-Tropical species near the coasts of Florida as against 158 species in Europe.

At least six North American species of forest trees, according to Brandis, are also indigenous in Europe. being-

Cercis canadensis = Siliquastrnm Diospyros virginiana = Lotus Celtis occidentalis = austra = australis Platanus occidentalis = orientalis Ostrya virginica = carpinifolia Castanca americana = vulgaris.

All these species now grow naturally in Europe south of the Alps, and since many American forest genera existed in Europe in Tertiary times, whilst only five European forest genera (Ceratonia, Laburnum, Olea, Syringa, Laurus) are not found in America, it is possible that other species formerly common to both countries were destroyed in Europe north of the Alps by the Glacial epoch

It would take too long to describe each region in detail, and I must here merely glance at them in the

briefest manner.

A small outlier of the West Indian tropical flora extends into the south of Florida, and is followed by a broad zone of evergreen broad-leaved forest, of which Magnolia grandiflora is the chief representative We then get the pitch pinc forests on the sandy formations of Florida, Georgia, North and South Carolina, extending westwards to Alabama and Mississippi. The wood of the pitch pine (P australis) is the best conferous wood in the world, but the forests are being utterly ruined. They are tapped in the most wasteful manner for turpentine, 8,000,000 dollars being the estimated local value of the and, according to Mayr, already wide belts of white sterile shifting sands border both sides of the railways of the Gulf States, showing what the poorer tracts of the country will come to, if the farmers do not give up then pernicious habit of burning thousands of square miles of forest every year

Another tree of the Southern Atlantic zone is the swamp cypress (Taxodium distribum), growing on annually mundated land, and presumably safe from fire, if

not from ill-regulated and wasteful felling

The valuable pencil cedar (Juniferus virginiana) also flourishes at its best in the Southern Atlantic region, but grows almost everywhere in the United States and British America, from latitude 54" southwards To the north and in the prairies it has, however, only a stunted growth Hardly any sound wood of this species is now procurable, as I learned last year from Messrs Faber and Co at Nuremberg. Next to this zone comes the description of the broad-leaved deciduous forest of the temperate region, containing many oaks, walnuts, hickories, and the tulip tree (*Liriodendron tulipifera*) The heavy seeded trees are found chiefly in the south, and lighter seeded ones,

as maples, birches, and elms, more to the north
There is a long account by Brandis of the prairie region,
and the region of thinly-stocked forest bordering on it, and it appears that here, as cultivation extends, and the firedo not sweep over such vast extents of land as they did formerly, woods of Mesquit bean (Prosopis Julifiora), and other trees are spreading by seed or coppice shoots, in Western Texas, and also in Wisconsin, Illinois, Iowa, and other Street Ministers or the street was a series of the street with the street was a series of the street was series with the street was series w and other States. Much has been done in the prairie region by plantations, and these succeed admirably wherever the climate is sufficiently moist, but in the central and western parts of Kansas all planting has hitherto failed, owing to the extremely dry climate.

hitherto falled, owing to the extremely dry climate. In the northern pine zone of the Atlantic forest region, Pinus Strobkej, the Weymouth or white pine is the most important speeces, and formerly covered normous tracts from the Gulf of St. Lawrence to North Georgia, and beyond the sources of the Mississippi. At present, the only considerable supply of white pine is in Canada, and in the lake districts of the States of Michigan, Wisconsin, when the control of control of control of control of considerable control of control control of control of control of control control of control control of co

NO. 1125, VOL. 44]

and Minnesota. The timber operations in the white and Minnesota. The timoer operations in the white pine forests have only one object, which is to bring as much timber as possible out of the forest in the shortest possible time, and to make money Only the best trees are felled, and the rest burned. A forest after a timber gang has left it presents a remarkable appearance: between the standing blackened and partially charred stems of the broad-leaved and other trees which have not stems of the bload-leaved and other trees which have had been felled are the stumps of the felled pines, whilst the ground is covered with wood, which would not have paid for its removal, and rots, or is burned by the annual fires.

In 1880, there were in the three lake districts 7000 million cubic feet of standing white pine timber, whilst in the last ten years 6205 millions of cubic feet have been felled and exported, 750 millions in 1889 alone There is, therefore, little more left than can be exported in a single year. Many of the large saw-mills have already been obliged to stop work, or get timber from Canada. Chicago, which owes its rapid rise to the timber trade, imports yearly 166,000,000 cubic feet of white pine timber This is about three-fourths of the whole forest yield of Prussia, the produce of 6,750,000 acres or 10,547 square nules of forest Besides the Weymouth pine, Pruss Banksiana, the grey pine, and Pinus resinosa, and various broadleaved trees are found The sub-Arctic region of Alaska and British North America is poor in species, Puca alba and mgra, the white and black spruce, being characteristic

Merely glancing at the North Mexican forest region, with forests of Prosopis juliflora, and grassy tracts containing gigantic cacti, and Yucca baccata, a palm hly, attaining 40 feet in height, we come to the Pacific forest region, where the Douglas fir, Pseudotsuga Douglass, is the most important tree, and yields, in suitable localities, perhaps the greatest quantity of timber per acre of any

known species.

62

We finally come to the red wood forests of the Pacific coast, where Sequoia sempervirens prevails, its congener Sequoia gigantea only occurring over a limited area Unregulated fellings also prevail in the Douglas and red wood forests, and their supply cannot last much longer

Besides the wholesale destruction of forests which goes on in America, and has already driven the United States to remove all duty from Canadian wood, the most appalling destruction is now being annually caused by the floods which pour down the slopes of the mountains, bringing down boulders, stones, and gravel on the cultivated lands below Mayr has seen standing trees covered with mud up to a height of 15 feet in some of the Southern and Central States, whilst hundreds of magnificent trees lay uprooted in the full vigour of their growth. This clearly be traced to the destruction of the hill forests

How long will rulers of the United States shut their eyes to the appalling waste of the resources of their country which is still rampant! Brandis hopes that private capitalists may invest their money in forests, tempted by the rapid rise in the price of wood, and may manage them properly; but all European experience points to the necessity of State forests, and a trained State Forest Service to manage them, as the only efficacious remedy against the impoverishment of the soil and natural resources of America. W. R. FISHER.

DAILY INTERNATIONAL WEATHER CHARTS.

AT the meeting of the Meteorological Congress at Vienna in September 1873, General Myer, the Chief Signal Officer of the United States Army, submitted the following proposal:—
"That it is desirable that, with a view to their ex-

change, at least one uniform observation of such character as to be suitable for the preparation of synoptic charts be taken and recorded daily and simultaneously at as many stations as practicable throughout the world."

Although various suggestions had been made before, and synoptic charts had been previously constructed for large areas, this proposal was a bold step in advance, as the charts hitherto published—those of the English Meteorological Office excepted—were mostly synoptic only, but not strictly synchronous, whereas the plan now proposed was to treat the whole observational area of the globe as a unit, and to represent the actual conditions existing at the same instant of physical time.

The proposal was well received, and on January 1, 1875, General Myer was able to publish his daily International Bulletin, and to supplement this, on July 1, 1878, by the daily International Weather Map These publications were continued until the end of March 1884, after which time the daily Bulletin was discontinued, but the chart was issued on an enlarged scale, containing data referring to pressure and wind direction and force at all reporting stations in the northern bemisphere and over the northern portions of the Atlantic and Pacific Oceans, and this has been published up to the end of December 1887. We have before referred to the ability with which this great undertaking has been carried out by the Signal Service. The necessity of obtaining strictly simultaneous observa-tions was generally acknowledged after the discovery of Buys Ballot's law of the relation between wind force and barometric pressure, about the year 1857, and it is almost entirely due to the construction of synoptic charts over large areas that so much progress has been made in weather prediction in the last quarter of a century. This progress would hardly have been possible while each progress would nargy nave been possible while each country dealt exclusively with its own area, notwithstanding the great advance made over the old system of dealing with means of observations by the publication of telegraphic weather reports and weather charts But notwithstanding the progress already made, we are still unable to foresee what may occur for more than a day or so in advance Much more research is required, and the thousands of observations now taken on land and sea over the globe should be plotted at least once a day We should therefore much regret the discontinuance of such work as that now before us, which deals with nearly half

the globe To take one or two of the facts shown by the charts themselves: the very severe gale which visited these islands on December 8 and 9, 1886, in which about the lowest barometer reading on record was observed, will be remembered in connection with the capsizing of the Southport and St Anne's lifeboats near Formby, resulting in the loss of twenty-seven lives out of twenty-nine which constituted the two crews. In a paper upon this storm, read before the Royal Meteorological Society on April 20, 1887, by Mr. C. Harding, it is stated, after a careful examination of the materials then available, that "the Atlantic was in such a disturbed condition at this time that it is not possible to track the passage of the storm across the Atlantic with any certainty" The daily storm across the Atlantic with any certainty" International Charts, however, show the position of the storm day by day, and also that it did actually cross the Atlantic from shore to shore, and was central over the Gulf of St. Lawrence on December 3.

Another instance of remarkable weather, it will be remembered, occurred in June 1887—the Jubilee year; the weather was remarkably dry and fine in this country, there being an extraordinary drought of about thirty days. The charts for that period show that similar anticyclonic conditions also embraced a very large part of the eastern portion of the Atlantic, and extended abnormally over a portion of Europe; while the travelling disturbances are plainly shown to be confined to the American side of the

It is only Government organizations that can undertake the laborious work of producing such charts; but when they are published, the matter should not be left there: the meteorologist should make use of the materials provided for him, and endeavour to solve the problems which underlie weather changes and the general movements of the atmosphere.

IOSEPH LEIDY, M D.

THIS well-known American naturalist was born on September 9, 1823. He very early in life showed a fondness for collecting and observing insects, one of his first contributions being a paper on the mechanism which closes the membranous wings of the genus Locusta, pub-lished in 1845 in the Proceedings of the Academy of Natural Sciences of Philadelphia Having taken his degree in medicine, he devoted himself more and more to the study of natural history, and few men of any nation have left behind them a longer list of work done than this distinguished man, whose death we announced in a recent number. Leidy was gifted with great powers of observation, he possessed a correct eye and steady hand for the delineation of whatever objects he was observing, he was endowed with a faculty for work; and as he had also an excellent memory, one reflects upon his half-century of work with less of surprise than admiration To give an account of his writings would be to write a volume, to give but their titles would be to fill many of our columns, so that it must suffice to call to mind rather the subjects about which he wrote than the writings Commencing with a study of entomology, and working more at the anatomy than at the general morworking more action anatomy man at the general mo-phology of macets, he quickly passed on to the study of the entophytic worms, his "Flora and Fauna within Living Animals," published as one of the Smithsonian Contributions in 1852, having made its mark at the time Then he took up the fresh-water Polyzoa, his labours on which will be understood only when a monograph on this group as inhabiting America comes to be published Leaving for a time the study of invertebrate forms, he next entered on the field of research among the fossil vertebrates, describing in quick succession a number of remarkable fossil reptiles and fish, and he was the author of the first volume of the quarto series of reports issued by the United States Geological Survey of the Territories, under the title of "Contributions to the Extinct Vertebrate Fauna of the Western Territories" It was during his journeys to the Western Territories, that, not content with investigating the fossil vertebrates of the district, he worked very diligently at the study of the microscopic forms of life which inhabit the waters met with therein, and these researches, so far as one group of animals is concerned, were happily published by the United States Geological Survey in 1879, in one large quarto volume, "The Fresh-water Rhizopods of North America," which is illustrated by forty-eight coloured plates after Leidy's own drawings This work on its appearance was received with great enthusiasm, and is still a worthy model for a monograph During all these years, and amid so many and so varied labours, Leidy still discharged his duties as Professor of Anatomy to the University of Pennsylvania, and also of teacher of natural history to the classes of boys and girls at the Swarthmore College. No doubt many of these latter pupils will now call to mind the warm personal interest their master always took in their labours. In one of his books he tells us that since he was fourteen years of age the study of natural history was to him a constant source of happiness, but that on this joy a shadow was constantly cast when he thought how few, how very few, of those around him gave any attention to intellectual pursuits of any kind, and it saddened him to feel that the command "that man shall not live by bread alone" remained so unappreciated by the great mass of even so-called enlightened humanity. The results of Leidy's intellectual pursuits will long remain to testify to the manner of man that he was.

THE SCIENCE MUSEUM.

THE discussion on this all-important question continues I has discussion on this all-important question continues in the press. The Whitsuntide holidays have prevented any questions being asked in the House of Commons, where the feeling is very strong against the action of the Government.

As before, we reprint the most important items in the scussion. These consist of letters from Sir H. Roscoe. discussion and Profs Armstrong and Ayrton to the Times We commend to our readers the reference by the latter to Mr Goschen's treatment of the deputation, and also their judgment as to the present position of science in this country, and the teaching of it in London, as compared with Göttingen and Zurich No one can speak with greater authority than Profs Armstrong and Ayrton on this subject

Our administrative system, however, is such that the present question, which is acknowledged to be of such high importance, is being settled exclusively by officials who are quite ignorant of science. This is not said to their disparagement . it is only a statement of fact. I he letters run as follow '-

ONE cannot but feel much sympathy for Ministers, on the one hand pressed by the advocates of scientific and technical education, and on the other nervous at the prospect of not securing the gifts of the munificent but somewhat exigenst art donor the gitts of the munificent but somewhat exigend art donor. But the question is so vitally important from the point of view of seence that I feel sure no excuse is necessary if I urge most stremously that an irrevocable step he not taken without full and careful consideration, and, further, that a definite scheme for providing for the science collections and Science School be formulated before what many of us believe to be a most unwise ormulates before want many of us believe to ne's most unwise interpolation of an art gallery, on land which when bought was universally believed to have been acquired for scientific ends, as finally decided on At the present moment it is impossible to say under which thimble the scientific pea is housed, and it was no doubt due to

this that the discussion which the deputation had with the Chancellor of the Exchequer and Lord President of the Council

on Tuesday last was to some extent abortive

The Chancellor of the Exchequer, in reply to myself on
March 18, said —

"It would be possible to make adequate provision for chemical and physical laboratories on the land between the Imperial Institute Road and the Technical Institute. This site adjoins the east galleries, and it is in these galleries, together with the west and southern galleries, and a proposed cross gallery joining the cast and west galleries, that the science collections may ultimately be bound? be housed

on nouses. April 15 the impracticability of the scheme of patting part of the Science school at the south end of the eastern gallery seems to have been discovered. For on that day Mr. W. H. Sunth, in reply to Mr. Mandella, propounded another scheme for the Science School, while leaving the collections to be housed in the east and west and cross galleres.

collections to be housed in the east and west and cross gainers.

"A portion of these warnt lands" (facing the Imperial Institute)" can be unliked for the extension of the College of Institute) and the College of Institute of the College of Institute of the College of Institute of Institute

the Science College."

By the former plan a portion of the Science School would no doubt have been in immediate contact with the splendid picture gallerist in which the science objects were to be loaded; but it gallerist in which the science objects were to be loaded; but it should be supported to the science objects of the science of

When receiving the deputation on Tuesday last, a third scheme was suggested, if not distinctly counciated, by the Chancellor of the Exchequer, that the Science School extension and the Science Museum should be built on the other side of the plot Science Museum should be built on the other side of the plot given to the Art Gallery, but both on the ground recently The two smiles of the plot of t

square feet of exhibiting space, and that more than that area can be obtained on the vacant ground opposite the Imperial Institute But it must be remembered that, as stated by our Committee, this space did not provide for offices, workshops, &c —a con-siderable item; that it did not in any way provide for the extension of the Science School; and that it was made some time before an immense impetus was given to technical educa-

tion by the I echnical Instruction Acts and the grants under the Customs and Excee Act of last year curred—omatting the strip part of which has already been sold, and the remander of which is gruing to be sold for pravide dwelling house—is about one-third of the land devoted to the Natural History Museum, and almost exactly of the same area as that aiready covered by the Natural History Museum buildings, which are shortly to be

Is it unreasonable for the scientific man to urge that this vacaut land is not too much to provide for the whole range of sciences other than those accommodated in the Natural History Museum, for a proper Museum of Machinery and Inventions, for a large extension of the Science School; and possibly for the collections from the Jermyn Street Museum? Surely there can be but one answer to this question.

Why—and we have never yet obtained an answer to this

inquiry—will not the munificent donor be satisfied with another sile? Why are the existing physical laboratory and scientific class rooms to be removed, to allow an art gallery to be interested to the sile of t should look a little ahead, and not now initiate another hugger-mugger arrangement of the collections and schools at South

Kensington, which all will lament in a few years?

10 Bramhnm Gardens, S W, HENRY E ROSCOR
May 15

NOTWITHSTANDING that the recent deputation to the Pre-sident of the Council and the Chancellor of the Exchequer was headed by Sir William Thomson—the man of science whom was headed by Sir William I hom-on—the man of science whom we in this country regard as first among all others, both on account of his individual achievements and on account of his occupying the representative position of President of the Royal Society—not one single word was said by Mr. Goschen in explanation or justification of the course which he has adopted; explanation or justification of the course which he has account we therefore venture, with all respect, to assert that the Royal we therefore venture, with all respect, to assert that the Royal with one of its Fellows—for Society has just cause to complain when one of its Fellows-Mr. Goschen is one of us-thus treats representations urged by its President

Where the science collections are to be lodged, where the extensions of the Science Schools are to be placed, are in themselves all important questions; but a still graver issue remains whether a weight of opinion of the magnitude represented by the memorial recently published in your columns is to be entirely set aside because an anonymous donor has offered £80,000 plus set saide because an anonymous donor has offered £50,000 plus a collection of pictures, valued at another £55,000 That a Government which has at its head a Prime Minister whose mirrest in secence is so marked, should that unlerged the opinion offered by so representative in body of men, is one of those things which even an Englishment can sexercy understand: in OWC among the picture of the pic

We cannot help tunking that a mistake has been made in calling public attention to occutavely to the housing of the scenes collections—the extension of the Science Schools appears called of last to what is going on abrond, appearing in called of last to what is going on abrond, appearing in castellite instruction, and to the effect that is being given to scientific instruction, and to the effect that is being produced on manufacturing industries of all kinds by the high develop-ment of science and of the application of every kind of selentific

requirement. Unfortunately, in this country such matters have not yet entered into the domain of practical pointes. But in the oplasion of many among as there cannot be a question that almost superhimman efforts are necessary if this country is to regain the opation which it has given away to foregamen by it neglect to apply the highest developments of chemical and physical science to industry.

The accommodation at present afforded by the Royal College of Science laboratories is not only inadequate, but beneath con-tempt in comparison with that to be found in Continental clies, such even as Gottingen and Zurich, for example; and those of us who have some knowledge of modern requirements know full well that every inch of space on the Imperial Institute Road side of the block of land on which stands the Natural History side of the block of land on which stands the Natural Hatsory Masseam will before long be required for the purposes of the Royal College of Science. The intrusion of an art gallery into this space would have a most disastrous effect by irretirevally lead to the standard of the Science in developing intruspinous flow instruction must lead even that country to fully appreciate the value of experimental values, and to insure on proper laboratory accommendations, and to standard on proper laboratory accommendations, and to small compression of the properties of the standard of the standa

experimental studies, and to insist on proper informatory accom-modation being provided. Surely the munificent donor will accept for his gallery some other site equally good for art, and not insist on striking a blow at science by taking a piece of land already set apart for laboratories

HENRY E ARMSTRONG, Secretary of the Chemical Society.
W. E Ayrton, President of the Physical Society.

It seems probable that, as the discussion goes on, some side light will be thrown upon the motives of those who have the "munificent donor" in hand. Although we have not room for the whole of a letter from Mr Marshall of Edinburgh, the general drift of it may be stated as follows -

Mr Marshell's man point is that, according to the statements made by hir Frederick Leighton in his speech at the Royal Academy banquet, the new gallery is to be used as "a search and the statements and the statement of the stat early Italian art, is fully if not excessively represented in ou National Gallery, and while n few of our great native artists (notably Turner and Constable), and many of our small ones, are represented far beyond what is necessary or even desirable our native water-colour art is practically not recognized at all, and many of the very greatest of our masters in our, who were (most of) them most recommend to the colour masters in our water of the colour masters of the colour master of t our native water-colour art is practically not recognized at all, now endeavouring to steal the stones that others nave quarrous and hewn for the martys' moment in order to erect with them another comfortable massion for themselves." Mr. Marshall is of opinion that "provincials" have opportunities more than enough of seeing contemporary art. Their wish now is to have a chance of studying fine specimens, authoritatively selected, of the acknowledged masters of our English school. The possible existence of such special motives as those here suggested among the persons who are attempting to get a grant of land for the carrying out of their so-called national objects should form an additional inducement to men of science to redouble their efforts.

NOTES.

This general programme for the Cardiff meeting of the Binsh Association has now been arranged The first meeting will be held on Welnesday, August 19, at 8 p m., when Sir Frederick Alek, K.C.B., will resign the chair, and Dr. Williams Hüggins, President-elect, will assume the presidency and deliver an address. On Thranday evening, August 20, at 8 p m., there will be a sorte, on Friday evening, August 21, at 8 30 p m. will be a sorted. On Friday evening, August 21, at 8 30 p m. and absocurs on You From Lin Chair in the Life of Aquatic Insects, "by Frof L. C. Minll, on Monday evening, August 24, at 8 30, p m. a sorted. On Wednesday, August 26, the concluding general norming will be beld at 3.0 p m. and the sorted of the August 25, the concluding general norming will be beld at 3.0 p m.

THE arrangements for the International Congress of Hypiene and Demography are nearly complete, and the programme, corrected up to May I, has been assued in the form of a pamph-It has been definitely fixed that the opening meeting, at which the Prince of Wales is to preside, shall be held on Monday, August 10, at 3.30 The sections (of which there are ten) will meet on the four following days from 10 to 2 The six medical and scientific sections will meet in the rooms of the Royal and other learned Societies at Burlington House The University of London will give the use of its large theatre to the section for the hygiene of infancy and childhood, and two examination halls to the sections for architecture and engineering The division of demography will meet in the Theatre of the School of Mines, Jermyn Street Much attention is being given to the necessary social preparations, and there is already a long list of proposed entertainments and excursions

A CEMERAL meeting of the Federated Institution of Mining Engineers will be held in London on Thursday, the 28th inst, at 12 noon, and on Fridsy, the 29th, at 10 a m, in the rooms of the Institution of Civil Engineers, 25 Great George Street, Westimister Various works will be visited on the 29th inst.

THE Committee of the Cardiff Naturalists' Society have put on foot a petition in favour of Mr. Pease's "Bill to Amend the Wild Birds' Protection Act, 1880." They are appealing to other scientific societies to join with them in order to make the petition as effective as possible

AT Mowbray, a suburb of Cape Town, Mr Cecil Rhodes has bought for £16,000 land on which, it is understood, the proposed University is to be built

This death of Prof. Carl Withelm von Nageli, the emment botamist, is announced. He died at Munich, on the 10th inst, in in the 74th year of his age, and will be buried at Zurich, in accordance with a with expressed before his death. Prof. von Nageli was a Foreign Member of the Royal Society We hope on a future occasion to give some account of his scientific labours

This Australian papers announce the death of Dr. Richard Schomburgh, brother of the lates its Robert Schomburgh, and for many yearn Director of the Botanic Gardens at Adelands, South Australia Dr. Schomburgh was associated with his brother an the Boundary Denarcation Commission of British Gunsan in 1849, and, some yearn later, settled with another brother in South Australia as a farmer and wine-grower On the death of Mr. Finnels, in 1866, he was offered, and accepted, the post of Director of the Adelande Botanic Gardens, which be held with much distinction until his death. He was an

enthusiastic horticulturist, rather than a hotanist-that is to say. as an author; and his services in connection with the establishment he directed were very highly appreciated, as the sketches of his career testify. Indeed, so long ago as 1883, a large number of his admirers subscribed the funds to procure his portrait for the Museum of Economic Botany, founded by himself His literary work commenced, we believe, with his "Reisen in Britisch Guiana in den Jahren 1840-1844," the third volume of which is devoted to a "Versuch einer Flora und Fauna von Britisch Guiana," in which Schomburgk had the assistance of several other botanists. This work has not yet been superseded, though its usefulness is unfortunately much limited by the publication of a large number of new names without descriptions. In 1876. Dr. Schomburgk supplemented this work by his "Botanical Reminiscences of British Guiana" But his most valuable literary work relates to the botany, to the agricultural and horticultural capabilities of his adopted country, and expecially to the Botanic Garden, of which he was to a great extent the creator. His name will long be remembered in connection with this establishment, which is, it is asserted, the "most complete paradise of flowers in the southern hemisphere."

ACCORDING to the Calcuta correspondent of the Timet, the Miranza Expedition, under Sir W Lockhart, has obtained much valuable geographical information about places which, although within a few miles of the fronter, have been follered unwisted by Europeans. The surveys effected by the Kuram field force during the Afghan war have been carried on to the Karanana Valley.

A Russian scientific expedition, under the command of Captain Bartshevsky, has left Samarcand for the exploration of Southern Bokhara, the Pamir district, and Kafiristan

On Saturday, May 30, at the Royal Institution, Prof A H. Church, Professor of Chemistry in the Royal Academy of Arts, will begin a course of three lectures on the scientific study of decorative colour

THE Rev H N, Hutchinson has undertaken to write for Messr. Swan Sonnenschein and Co 's "Introductory Science Text-books" a manual of physical geology A second edition of Dr Hatch's "Petrology" in the same series, reviewed in our columns latt week, has already appeared.

MESSAS WINITAKE'S CO have in preparation a "Labrary of Popular Science" Among the works to be included in it are "Astronomy," by G F Chambers, "Light," by Sr H Trueman Wood; "Chemistry," by T Bolas, "Mineralogy," by Dr F. II. Hatch, "Electricity and Magnetism," by S. Bottone; "Geology," by A J Jukes-Brawn; "Botany," by G Massee

MR J ALLEN BROWN has expounded in the West Muldlesex Standard an excellent scheme-now printed separately-for a technical institute and museum for the Ealing Parliamentary division of Middlesex. This division comprises Ealing, Acton, and Chiswick, and Mr. Brown's proposal is that a technical institute and museum should be established in whatever position may be most convenient for these localities. An essential part of his plan is that the instruction shall be imparted by specially qualified teachers and lecturers, and that their duties shall be "migratory or peripatetic," so that classes may be conducted or lectures given in any part of the division, and on any of the subjects contemplated under the Technical Instruction Acts. We commend Mr. Brown's scheme to the careful attention of the Middlesex County Council, which will soon have to decide as to the distribution of the funds placed at its disposal for technscal instruction. There can be no doubt that the proposed institutions would be of immense advantage to the three districts, for Mr. Brown has a very enlightened conception of the true nature of technical instruction. What he wishes is that the young workman shall acquire "a knowledge of the scientific or artistic principles which are applicable to his trade or industry," and that by the development of his powers of observation and insight into the laws which govern all things "he may afterwards be eaabled to effect improvements and excel to a greater extent thus heretofour; in the work he desires to accomplish."

66

THE GUILDIGEN Society of Sciences has recently offered the following prise in physus for Scienceber 29, 1893.—From the researches of W kongen and A Kundt on variation of the optical properties of quarts in the electric field, there appears to be a close connection between the electro-topic phenomena and the elastic doffunctions which that piece determ is butance shows under the action of electrostatic forces. An extension of these inquiries to a series of piece decirie cryatals with various properties of symmetry seems highly desirable. The unweigitation should also be directed to distriming whether the electro-opinc phenomena in pixzo-electric crystals are easiest exclusively by the desformations courring in the electron field or, beaudes, by a direct action of the electrostatic forces on the lighth-motion. Priv. £35

THE German Society for the Encouragement of Industry offers the following (among other) prizes. (1) How far is the chemical composition of steel, and especially the amount of carbon present, a measure of the usefulness of cutting tools? Prize, a silver medal and £300, date, November t5, t89t (2) A silver medal and £150 for the best chemical and physical investigation of the most common iron paints Date, November t5, t894 (3) A gold medal and £150 for the best work on the magnettsm of iron This should comprise a critical comparison of previous observations, also personal observations on steel and wrought iron bars of the most various chemical composition possible, examination being made both of the strength of temporary magnetization with absolutely measured and varying magnetizing force, and the strength of permanent magnetism and its durability with regard to temperature-changes and vibrations. Date. November 15, 1893. (4) Investigation of the trustworthiness of the usual methods of determining the carbon in iron Prize, a silver medal and £150; date, November 15, 1892).

THE extraordinary collection of mummies, papyri, and other objects of antiquarian interest recovered last February at Deir-el-Bahari is now safely housed in the Ghizeh Museum According to the Calro correspondent of the Times, all the objects are in good condition, although some anxiety was caused by the protracted journey by boats from Luxor The correspondent says that the mummies mostly belong to the 21st Dynasty, and, though styled Priests of Ammon, are supposed to be the corpses of generals and other official dignitanes who bore ecclesiastical besides other titles. The 163 mummies and the 75 papyri are not yet unrolled, and it is difficult to form an estimate of their archeological value, as many of the sareophage bear different names on the outer and inner casings. whilst others have the names usually inscribed on the outer casings intentionally effaced. M. Grébaut thinks that, owing to this circumstance and the magnitude of the collection, some time will be required before any important communications can be made to the scientific world.

A SERIES of experiments has been lately made by Herr Robert (Archive juri Hyperace), with regard to the familiar fact that not only dry high temperatures are more easily borne than moist, but dry cold causes much less discomfort that moist cold. Dogs, fasting or fed, being observed in an all-calorimeter, it appeared that, in all cases, most air increased the loss of the best by conduction and radiation. For every variation of the air-moisture t per cent, beat was parted with to the extent of 033 per cent. In a persons ineveigation, Herr Robert

demonstrated the lessened yield of water by evaporation from anumals where the ar-monature is increased, involving leasened loss of heat. Here, then, are two antagonistic influences. He subspoted to regard the increased radiation and conduction in most as as the primary action, and the disminished evaporation as secondary. The colder feeling of most to dit has day is readily explained by the increased heat radiation. In most hat, with the sense of oppression it brings, this factor passes rather into the background. The degree of temperature, and offect the amount the contraction of the complex nature, also affect the amount the manufactors.

THE Meteorological Council have issued a publication containing the hourly means obtained from the self-recording instruments at their observatories for the year t887. This work constitutes a new departure in the use made of the records of the self-registering instruments, and one which we think will be of much practical use to meteorologists. The publication of the hourly observations in extenso, at the request of a number of scientific men, began with the year 1874, and was continued until t880, in a lithographed form, and the daily means were added in t879, from the year t88t to t886 they were issued in a printed form The Council, after careful consideration, have now come to the conclusion that it is preferable, for a time at least, to publish mean values only; hitherto no hourly means had been published by the Office, but in the present work these have been grouped into five-day and other periods, in a convenient form for discussion, and the necessity for dealing with an excessive number of values has thereby been obviated, while many useful tables not included in the old series have been added. It is proposed to calculate the means similarly for earlier years, while the original records will be carefully preserved, and will be available, should they be needed, for any special research.

THE Annual Report of the Director of the Royal Alfred Observatory, Mauritius, for the year 1889 shows that the island has again enjoyed immunity from storms; the greatest hourly velocity of the wind was 31 miles. The almost total absence of tropical cyclones in the South Indian Ocean during the year is considered by Dr. Meldrum as another confirmation of the law that these cyclones are fewest in number and least intense in the years of least solar activity. The mean temperature was 0° 7 below the average for the last fifteen years, and below the average in every month except July and October The maximum shade temperature was 93° I on March 27, and the minimum 52° 4 on June 18 The rainfall was 8 56 inches above the average, the greatest fall in one day was 3 88 inches on March 11, although this amount was much exceeded in other parts of the island On January 1, a waterspout burst on the Pouce Mountain, Port Louis was flooded, and some persons were drowned. The collection of observations made at sea is actively carried on; 324 log-books were received, and the observations duly tabulated The Report also contains observations made at the Seychelles and Rodriguez.

In a paper receasily published in the Metamologische Zutschrift, Prof. Hellmann, of Bertin, shows, from observations taken at different British, Continental, and American stations at which barggraphs are used, that there actus a close conscidence in the daily range of the monthly extremes and in that of occurrence of the highest and the lowest readings of the barmeter during a month agree almost completely with the hours of occurrence of the highest and the lowest readings of the barmeter during a month agree almost completely with the times in which the normal daily range has its maxima and minima, both curves being so multiar in abape that it may be possible to judge of the general character of the daily range of the barometer from knowing only the hours at which the monthly extremes mostly occur. Hence, as the lowest readings of the barometer are accompanied by cloudy and stormy weather, during which the effect of the solar radiation upon the surface of the earth and the heating of the lower strans of the strong-fere are quite insignificant. Prof. Hellmann concludes that Prof. Hann and others are light in assuming that the normal duly range of the barometer is chiefly an effect of the absorption of the solar ray; in the upper stans of our atmosphere. Prof. Hann has applied the harmonic analysis to the numbers furnished by Prof. Hellmann, and, by combining several stations in a group, has found the coefficients of the periodic formula to be practically the same as those for the normal duly range. We should, however, like to see a further confirmation with respect to the continuation of the continuation of the confirmation with respect to the continuation of the confirmation with respect to the continuation of the confirmation with the confirmation with the confirmation with the confirmation with the other and the confirmation with the confirmation with the other and the confirmation with the confirmation with the other and the confirmation with the confirmation with

THE first paper in the last volume of Transactions of the Seismological Society of Tapan is by Mr. Bertin, and describes the double oscillograph and its employment for the study of rolling and pitching. It traces curves automatically, showing the motion produced in a floating body by waves The second paper is on the "Seiches" of lakes, by Dr F A Forel, of Geneva, and discusses those variations in the level of the water of lakes with the investigation of which the author's name has been associated for some years past. Prof. John Milne de scribes the remarkable instrument invented by him for measuring and recording the oscillatory movements of railway trains. Mr Mason contributes a paper, accompanied by carefully compiled tables, demonstrating the importance of elaborating some uniform system of timekeeping for the purposes of seismological observations Prof. C. G Knott, in his paper on earthquake frequency. explodes two of the time-honoured delusions of the popular mind in regard to earthquakes, viz that they are more frequent during the night than the day, and that their periodicity is connected with lunar culminations. Mr Otsaka gives an interesting account of the great earthquake that visited Kumamoto in July 1888, and Mr Pereira contributes a carefully compiled record of all the earthquakes noted by him in Yokohama from March 1885 to December 1889 Mr W. E. Forster writes on earthquakes of non volcanic origin, caused, it is suggested, by the displacement of masses of land beneath the occan The volume concludes with various reports and papers by Prof Milne, such as diagrams of earthquakes recorded in Tokio, a report on earthquake observations made in Japan during the year 1889, and an essay on the connection between earthquakes and electric and magnetic phenomena, which is full of matter of an interesting and suggestive kind.

ACCORDING to the Colonies and India, Mr. Alexander McPhee, a West Australian bushman, who has steadily been earning fame lately by his explorations in the central regions of Australm, started inland from Roebourne in July last on another tour of discovery, taking back at the same time an albino aboriginal whom he found and brought to Melbourne a couple of years since. News has been received from which it appears that Mr. McPhee, with the albino, Jun Gun, and a "black fellow" named Timothy, went along the coast some 250 miles to a station called Yinadong, when the party turned mland in an easterly direction After travelling about 350 miles, Mr. McPhee came upon another albino, a boy of fourteen years, whom he describes as the most extraordinary specimen of humanity he ever saw. One old man in this camp told Mr. McPhee that when he was a boy he heard of a party of whites and horses dying a long way inland. The old fellow could give no particulars about this party, but Mr. McPhee feels certain, owing to his acquaintance with the habits and customs of the blacks, and being thoroughly conversant with their dialect, that a party of white men perished about forty years ago somewhere in the

interior. He heard of Warbarton's party, and saw a native who told him that he guided them to vaier. He also heard of two parties of whites who had lately been in the desert, but turned hack From his turning point to the coast of La Grange Bay, Mr McPhee rectons he was about 250 miles in a south-cast officient of the coast of La Grange Bay, and on no occasion was it necessary to keep a watch. The country is described as very poor. The only blied solserved during the pourney were an old crow and a few sparrows about the water; not a track of a hangagoor ore min was seen.

SOME satisfactory statements as to the growth of collegiate education are made in the last official report on public instruction in the North-West Provinces and Outh Of individual colleges. Agra, at which the numbers in 1885 had fallen as low as 45, has increased within the last two years from 07 to 175, or by over 80 per cent, and the percentage of increase last year was in no case less than 20. The number of matriculated students. indeed, is rising so rapidly that the existing accommodation is said to be barely adequate, it will, the Government resolution says, become a question of urgent importance whether the in creasing number of students should be provided for by additions to the staff and buildings at the colleges now in existence, or by the creation of new colleges, or by the strengthening of the college classes at high schools and adding to their number. "Government," it is added, "will necessarily be guided to a great extent by the nature and direction of the local demand, as indicated by the willingness of the residents of the principal towns to contribute to the increased burden of expenditure " On its present basis, at all events, the higher education of India has received a fair share of Government support. But if it is satisfactory, says the Pioneer, to find that collegiate education in its present form is making decided progress, and that it is becoming possible to throw the cost of the advance on private shoulders, it is a distinct disappointment that not a word is said, as not a step has been taken, in those new directions of educational activity where other provinces have not only started, but made appreciable progress There may be two opinions as to the extent to which, or the means by which, it is possible to introduce technical education, but there can be no question that some movement is desirable. It may be hoped that the omission is due, not so much to a failure to estimate the importance of the subject, as to a desire to give it fuller treatment on a future occasion

Tits amount of apparent flatening of the vault of the heavest Prof. Remain has lately attempted to measure by noting the point which seems to baset an are extending from the senth to the horson. From \$3 observations at Hirscheept, the found that this point was at "47 # 2 0.08 above the horson. This indicates a ratio of the vertical axis to the horsonal of 1 ; 3 66. This apparent flattening has an annual period, and is dependent on eloud. The highest position of the baseting point was assigned in autumn (21° 98), the lowest in spring (20° 42). The vault become flatter the more the cloud. It teems least flat with a misry horson; and the flattening seems less by might than by day. Curously, seemed other persons whom Prof. Remann got to make the same determination all gave higher values for the angle

This settlement of a purely philological question (that, namely, as to the position of the French scenal), by a physical method, has been recently attempted by Dr. Pringhteim, off Bertin (Maturus, Radio 3). The instrument used was Noing and Scott's phonautograph, into which a number of Frenchmen were required to speak; the measurement of the record being afterwards to speak the measurement of the record being afterwards. This instrument renders possible at determination of the duration, pitch, and intensity of each vigible, and Dr. Pringsheim.

discusses its indications As a preliminary result, he finds that two-syllable words have the vowels pronounced with equal length and strength. Noteworthy differences appear in the curve of a word according as it occurs in the middle or at the end of a sentence. In the latter case, there is added to the characteristic word curve, a terminal curve with declining pitch and strength, which is nearly the same for different words, and corresponds to the sinking of the voice before a pause vowels and consonants show characteristic curves, and notably long wave-lengths occur with w. L. b. and d The duration of syllables varies between 0'1 and 0 5 second; and between the syllables of a word there are often pauses of 0 03 to 0'2 second The shortest syllable I in He, with rather slow pronunciation, consisted of 22 vibrations, yet the ear is capable of not only hearing the tone, but of detecting fine shades and differences in the mode of pronunciation. Further experiments in this direction, with an improved apparatus, are contem-

THE Perak Government Gazette states that a portion of an ethnographical collection formed by Signor G. B. Cerruti, In the island of Nias, has been recently acquired by the Government of Perak for the museum Pulo Nias is one of a chain of islands bordering the south-western coast of Sumatra. The population is said to be numerous and of one race, though divided into many tribes under independent chiefs. Headhunting is as common with them as it used to be in Borneo, and most of the houses have skulls hung up in them Their weapons consist of iron-headed spears, mostly barbed, knives of two patterns, somewhat resembling the Kadubong Achi, with shields of two distinct types No boxs and arrows or blow-pipes seem to be known, nor are throwing sticks applied to their spears, boats also are not used by them, though rafts are sometimes made to cross the rivers on. The ironwork of their weapons is fashioned by themselves, and the upright double cylinder bellows is used to supply wind to their forges-the same in every respect as those used by the Semangs of Upper Perak, and the far away Malagasy Helmets of black 130h fibre are worn, somewhat similar to the cocos-nut fibre ones of the Sandwich Islanders. Woven body armour is in use, in the shape of thick coats made of what appears to be the fibre of Hibiscus teleacens Buffalo hide armour is also said to be used, but is not represented in this collection Attached to the sheaths of some of the knives are four or five animals' teeth, such as tigers, rhinoceros, &c , also a small carved wooden idol, and one or more bamboo boxes containing stones In those examined there were twelve publics in each hox. These stones are supposed to have been taken from the spot on which a man had been slam charms are tied up into a bundle with red cloth, and bound with string on the upper front part of the sheath of the knife.

A COMPREHENSIVE study of the influence of forests on the daily variation of air-temperature has been recently made by Prof Muttrich (Met. Zests.), the data being from stations in Germany and Austria. Inter alsa, this influence is greater in May to September or October than in the other months In pine and fir woods it rises gradually from January to a maximum in August or September, then falls more quickly to a minimum in December, but in beech woods a minimum occurs in April, then there is quick rise, till the maximum is reached in July. The daily variation itself is greatest in May or June, both in forest and open country. The influence of the forest is to lower the maxima and raise the minima, and the former influence is in most months greater than the latter; in December and January. and occasionally in neighbouring months, it is less. The influence on the maxima in summer is greatest in beech woods, less in pine, and least in fir. The absolute value of the influence an woods of a given kind of tree is affected by the degree of density

of the wood, being higher the denner the wood. The character of the chunse (coann or continental) also affects the results From daily observations in forest and open country, every two hours in the second half of June, it appears talk, soon after 5 am and 8 p m , the air-temperature in the wood was equal to that in the open p that the maximum was about of 9 lower in the wood, and the minimum or 6 higher; that in May to September the difference sometimes resched $2^{**}7$; that the maximum in the wood occurred about half an hour later, and the minimum aquarter of an hour earlier, than in the open; and that the daily mean air-temperature was about $\frac{1}{2}^{**}$ less in the wood

THE Revue des Sciences Naturelles de l'Ouest gives an account of the life of Mathurin Rougult, one of the pioneers in the geology of Britishy. Rousult was born in 1813, of a very poor family At the age of ten, while engaged as a shepherd, he became interested in "stones" and "rocks," and began to make a collection. By the death of a relative he obtained possession of a small hairdresser's shop, where he worked on Saturdays and Sundays, spending the rest of his time in hunt ing for rocks. Although Geoffroy Saint Hilaire visited his collection of specimens, and was much interested in them, nothing would have been done for the poor young geologist-who lived upon something like five centimes a day-if it had not been for General de Tournemine, who, stationed with the garrison in Rennes, had been attracted by him It is said that one day he went into the shop, and, seeing an antique pistol which Rouault had bought for a few centimes to kill himself with, the general remarked, "That is just the pistol I am after I want it for my collection " And without waiting for an answer he took the pi-tol, and gave the young man 100 francs M de Tournemine went still further He revised a memoir which the illiterate geologist had written. This was read in the Academy of Sciences, and met with so much success that the author became well known. The town of Rennes gave him 800 francs a year to help him to live in Paris, and afterwards he was appointed Director of the Geological Museum of Rennes But he was dismissed on account of quarrels with some unintelli gent bureaucrat, and died in 1881. Before his time only five or six fossils were known in Britiany afterwards they numbered 500 or 600 He spent two years or more in making up Trinucleus Pongerards out of over 2000 fragments

An important paper upon the atomic weight and position in the periodic system of the rare element lanthanum is contnbuted by Dr Brauner, of Prague, late of the Owens College, Manchester, to the current number of the Berachte In his recent work upon the reduction of oxides by metallic magnesium Prof Winkler advanced the view that lanthanum is a tetravalent element of atomic weight 180, instead of, as has hitherto been accepted, a trivalent element belonging to the boron vertical group of the periodic system, with an atomic weight of 138 5 If lanthanum were indeed tetravalent with atomic weight 180, it would probably be the missing element between ytterbium and tantalum on the one hand, and cerium and thorium on the other Further, Prof. Winkler expresses the opinion that the old values of Rammelsberg, Zschiesche, and Erk, for the equivalent of lanthanum, are correct. These experimenters obtained the round number 45 for the equivalent, and this number multiplied by 4 gives Prof. Winkler's suggested atomic weight 180 If, however, multiplied by 3, the atomic weight 135 is arrived at, and Prof. Winkler argues that even if the element were trivalent its atomic weight would not be 138'5 but 135. Against these views Dr. Brauner brings forward the following experimental facts. In the first place, Hillebrand (working under Bunsen) found the specific heat of Bunsen's pure lanthanum to be 0'04475. No impeachment has ever been brought against this result, and Dr Branner

sees no reason why it should not be accepted. Making use of Dulong and Petit's generalization and multiplying this number by 138, a normal atomic heat of 6'18 is arrived at, whereas if multiplied by 180 the abnormal value 8 07 is obtained Again, an element of atomic weight 180 should possess a density of 8 2, whereas that of lanthanum is only 6.48, a specific gravity corresponding to an atomic weight of 138. Considering therefore the position of lanthanum in the trivalent boron vertical group assured, Dr. Brauner brings forward a redetermination of its atomic weight of his own in order to decide between 138's and 135 His experimental method consisted in converting known weights of the oxide into sulphate. The material employed was obtained by a lengthy process of fractionation with ammonium nitrate, the oxide eventually obtained containing the most positive of the certte earths (lanthanum oxide) and showing no traces in the spectrum of any others His value thus obtained is 138 2, a number closely agreeing with those of Cleve and Bettendorff The earlier and lower values of Rammelsberg and others are shown to be probably due to the presence of yttria, which was not detected by these observers, masmuch as the work of Thalen and Bunsen upon the spectrum of yttrium had not then been published. Hence lanthanum of atomic weight 138 2 retains the place in the trivalent group of the periodic system marked out for it by its well-known basic properties.

THE additions to the Zoological Society's Gardens during the past week include a Striped Hyana (Hyana striata ?) from India, presented by Mr. B T Ffinch, C.M.Z.S., two Hairyrumped Agoutis (Dasyprocta prymnolopha) from British Guiana, presented by Mr. H Barrington; two Brent Geese (Bernicla brenta), a Pintail (Dafila acuta 8), two Wigeons (Marcea penelope & 9), a Common Sheldrake (Tadorna vulpanser 9), two Golden Tench (T)nea vulgarss, var), nine Golden Carp (Carassius auratus), British, presented by Mrs. Atkinson , eight European Tree Frogs (Hyla arborea) from the South of France. presented by Mr Clifford D. Fothergill; a Crested Porcupine (Hystrix cristata) from India, a Tibetan Crossoptilon (Crossoptilon tibetanum 9) from Western China, deposited , two Swin hoe's Pheasants (Euplocamus swanhous & 9) from Formosa, two Japanese Pheasants (Fhasianus versicolor 9 9) from Japan, two Amhern's Pheasants (Thaumalea amherstur 9 9) from Szechuen, China, a Black-necked Stilt Plover (Himantopus nigricollis), a Cayenne Lapwing (Vanellus cayennensis) from South America. purchased, a Wild Swine (Sur scrofa 9) from Persia, received in exchange, two Indian Desert Foxes (Cams leucopus), born in the Gardens.

OUR ASTRONOMICAL COLUMN

THE PHOTOGRAPHY OF FAINT NEBULA -In the Journal of the British Astronomical Association for February, Dr. Max of the British Astronomical Association for Section 1988.

Well, of Heddeldery Claseratory, continues a note on a note on a note on a note of the section of

NO. 1125, VOL. 44]

the like-bodies having a finite area. The intensity of the image at the focus then varies as the fraction $\binom{d}{r}$, where d is the diameter of the object-glass, and f its focal length. If, therefore, the intensity of the light received with an aperture of zo inches and focal length of 100 inches be expressed by 0044, that of a portrait lens of 4 inches aperture and 12 inches focus so 11. This shows that in order to photograph the same faint nebula, the instrument of 20 inches aperture requires an exposure about three times at long as the 4-inch portrait lens.

Another paper having the same purport is contributed by Dr Holden to vol in No 14, of the Publications of the Astronomical Society of the Pacific, from which it appears that from 80 to 100 minutes' exposure with the 33 inch Lick telescope will give minutes' exposure with the 33 inch Lick reiescope will give about the same number of vlars as 205 minutes' exposure with Mr Roberts's 20-inch reflector. When, however, the amount of nebulosity depicted is considered, the advantage is considerably in favour of the short-focus reflector, a comparison of the results. obtained with the two instruments indicating that 15 minutes' exposure with the reflector is about as effective in showing the nebulosity of Orion as 60 minutes' with the refractor

VARIATIONS IN LATITUDE -Prof 11, G, van de Sande WARIATIONS IN LATITUDE—Prof 11, G, van de Sande Bakhuyren extends our knowledge of this subject in a paper contained in the March number of the Monthly Notices of the Royal Astronomical Society The conclusions deduced from th e investigation of observations of Polaris made befrom the investigation of observations of Polaris made between 1851 and 1852, and the interesting researches of Mr. Thackeray (Memoirs R A S, vol xlix p 239), may be summed up as follows—(1) The monthly discordances in the zenith distances of Polaris are, for the greater part, not caused by a real variation of faittude, but theigh by an effect of temperature (2) It is not possible to explain those discordances by an error in the indication, of the exterior thermal part of the exterior thermal part of the properties of the exterior thermal part of the exterior t mometer, or by an influence depending only on the exterior temperature (3) The discordances can be explained, for the greater part, by a cause depending on the difference of the greater part, oy a cause depending on the difference of the exterior and interior temperatures (4) Probably that cause is a refraction in the observing-room, and its effects are sensibly proportional to those differences of temperature. (5) The discordances corrected for that refraction are about the same for both culminations, and can be explained by a real variation of

An investigation of the mean North Polar distances of Polaris in both culminations observed at Greenwich between 1883 and 1889 leads to the conclusions (1) that it is probable that the observations of Polars at Greenwich confirm the variations of observations or learn at Greenwich country the warrations of lastitude observed elsewhere in 1884-1885 and 1889-1890; (2) that there is a very strong probability that the variations in these years had an exceptional character, and do not agree with the annual variations, deduced from the observations of Polaris at Greenwich during the period 1851-1882.

RE-DISCOVERY OF WOLF'S COMET (1884 III) .- Astro-RE-DISCOVERY OF WOLF'S COMET (1884 111).—Astro-monache Machachiem, No 3033, contains the information that Wolf's periodical contect was observed on its return by Prof Barnard, of Lick Observatory, on May 37932 (M.T. The following ephemens is from one given in Edinburgh Circular No. 15, by Prof. Berbench. The brightness of the comet at re-discovery has been taken as unity.

The comet will pass perihelion on September 3'3199 Berlin mean time. It is near a Pegasi at the present time, and may therefore be seen just before sunrise. The motion is towards

THE PARIS ORSERVATORY

THIS report opens with the address delivered by the Director,
Admiral Mouchez, before the Council of the Observatory
on February 24 last, the following is a brief summary of the

on February 24 last, the following as brief summary of the most important pounts touched upon more than the most important pounts touched upon problem of the building for the large equatorial could, in which the instrument is now being execute, and to the formation of a special service for spectroscopy, over which M. Dealandres has been put in charge mention of the problem of th the objects that physical astronomy studies in order to penetrate more and more deeply into the knowledge of the universe, admit more and more deeply into the knowledge of the universe, anni-indeed of new processes of observation of such delicacy that they are allogeber incompatible with the turmoil and dis-turbances of all kinds in a populous city. The instruments with large optical power lose nearly all their superiority, because they magnify the defects of an impure and disturbed almosphere at least as rapidly as the images of the stars

rease as repress as the images of the stars.

This is by no means the first time that this question of a branch establishment has been raised, but it looks very much as if it might now be taken up seriously. It seems that a proposal has been made to extend the railroad from Secux-Limours in the interior of Paris to Médicies and Cliunv. where it Limours in the interior of Paris to Médicis and Cluny, where it would join the metropolitan; if this project was carried out, trains would run as close to the Observatory as 150 metres, thus affording the assistants at the Observatory an interesting amusement in calculating the distances of these trains by the vibrations set up in the various instituments

A committee of inquiry, presided over by M Chauchat, has been formed to inquire into the situation, and the unanimous

opinion of all the astronomers questioned on the subject was that "the Observatory would be almost lost if this project was carried out according to the present conditions"

carried out according to the pretent conditions."

Of the other arguments put forward by Admiral Mouchez in favour of the branch establishment, the following may be mentioned. The lighting of the surrounding streets by means of the electric light. This, as he says, would obliterate all says. of the electric light. This, as he says, would obliterate all stars above the 11st Inagnitude, and perhaps even above the 11st In, to say nothing of the minor planets, nebulæ, and some comets. And with regard to photographing the heavens with moderate exposures, it would become nearly impossible owing to the fogging of the plates before the images are formed, the gas from fogging of the plates before the images are formed, the gas from the attreat lamps even now producing the effect on the sensitive plates. Referring to the opening and enlarging of the Rue Cassnip, he points out, that at no remore date, houses will be constructed from 20 meters to 25 metres to height at a distance of 100 metres, and just in the direction of the mendian line of the instruments, these, besides completely blotting out from view many of the arcumpolar stars at their lower culimation, will render the observation of those that remain difficult on

will render the observation of those that remain difficult on account of the smoke from the chimneys.
Following Admiral Mouchez's address are the reports, from each of the heads of the various departments, of the work done during the past year
With the mendiani circle no less than 14,374 satisn have been observed, actisuise of the 432 observations of the planets made with the same instrument. Observations of the planets made with the same instrument. servations which were commenced in the month of April with the equational could, bave been regularly pursued, and at present the results have been highly satisfactory. Not only "do we believe that we have settled in every detail the most precise rules for the application of the new method, but also we have obtained the constant of aberration with an exactness which surpasses all researches made up to the present time

The three equatorials have been used by M Bigourdan, Mdlle, Klumpke, and M. Boinot respectively, and with them observations have been made of comets, double stars, nebulæ, eclipses of Jupiter's satellites, occultations, planets, and double

M Paul Henry, who is chief of the photographic department, has been bussly cngaged among other things in making large chickit of different regions of the sky, several of which were prepared at the request of foreign astronomers.

The most unportant addition to the Observatory for the year

' "Rapport Annuel sur l'État de l'Observatoire de Pans pour l'Année 1890." Frésenté au Conseil par M. le Contre-Amiral Mouchez (Paris: Gauther-Villars et Fils, 1891)

NO. 1125, VOL. 44]

was the special service for stellar speciroscopy, which, as we have mentioned before, is superintended by M. Desiandres, have mentioned before, in superintended by M. Desiandres, outmost value to science, and the results obtained will be looked forward to with interest. With regard to this branch Admiral Monchez has given an extract from M. Desiandres' report on

After a short description of the meteorological work carried After a short description of the meteorological work carried to, together with the various other reports untailly inserted in this pumphlet, Admiral Mouches concludes with a brief reference to the Observatory School at Monisoarts, of which also he is Director. This school was organized under the patronage of Prance of a school for practical surriously, where "furnities officers, explorers, professors of science, and others could come and accustom themselves to make observations" Since the officers, explorers, professors of science, and others could come and accustom themselves to make observations? Since the year 1877 the Observation? has been freely opened to anyone, the only conditions being that those who go should have sufficient scientific knowledge to understand what is taught, and that there work should be regular "Doy we an idea of the range of the subjects that form the syllabus of instruction we caused the best term and the subjects that form the syllabus of instruction we caused bester that condense the methods of organizations as given in the

better (name conservations), both theoretical and practical report.

With regard to astronomy, both theoretical and practical lectures are given twice or three times a week. M. Bottel delivers a course on electricity and inagnetism which extends over four months, during which time the conducts the officers over all the large electrical manufactories in Paris. Lectures with the large electrical manufactories in Paris. Lectures them with practical instructions for the determination of the magnetic elements M. Thoulet treats of ocean geographic in a course that is of interest and use to sailors. The regulation of the compass, so important to day on account of our iron ships, forms the subject of a number of lectures by M Caspara, while photography is studied for two months under the superintendence of M. Guenaire

From this syllabus it will be seen that a good, practical, and sound course to open to all those who wish to take advantage of it, and in the list of explorers who have figured in the principal missions during the last fifteen years the majority will be found to have served at any rate a short period at the Observatory

In concluding his remarks, Admiral Mouchez, after referring to the school that was started in 1879, and which was suppressed some years after for reasons of economy, points out the necessity of giving every encouragement to the one that is doing such good work at Montsouris W I. L.

NOTE ON THE PHYSIOLOGICAL ACTION OF CARBON-MONOXIDE OF NICKEL [NI(CO),]

DY the kindness of Mr Ludwig Mond, we have had the opportunity of examining the physiological action of car-bon-monoxide of nickel, a substance of unique chemical com-position, represented by the formula Ni(CO). The general results of our investigation are as follows.—

(t) Ni(CO), is a powerful poison when injected subcutaneously

into a rabbit weighing I 5 kilo even with a dose of 1/30th c cm.
(2) The vapour of Ni(CO), in air, even to the extent of 0.5 per

cent, is dangerous.

(3) The symptoms are those of a respiratory poison, and are similar to those caused by carbonic oxide

similar to those caused by carbonic oxide
(a) The spectrum of the blood of an animal poisoned by
Ni(CO)₄ is that of carbonic oxide-hæmoglobin, and it is not
reduced by sulphide of ammonium.
(5) When the substance is injected subcutaneously it is

(5) When the substance is injected subcutaneously it is probably in part dissociated in the tissues, as there is evidence of the existence of nickel in those tissues, but the nickel also finds

the existence of nickel in Inose issues, but the nickel also made its way into the blood, and is found there.

(6) The substance produces a remarkably prolonged fall of temperature even when given in small quantities. In several instances, with lethal doses, the fall was from 2° to 12° C. This may be accounted for by the harmoglobin being prevented to a large extent from supplying the tissues with oxygen. Nico, as we may, for convenience, call this substance, makes it possible to give graduated doses of carbonic oxide, and thus reduce temperature

By John G. McKendrick, M.D., F.R.S., and William Spodgraus, M.A. M.B., Physiological Laboratory, University of Glangow.

by directly interfering with the responsion y axchanges occurring in the tissues. The objections to its set as an an antisyruct see that, owing to its posionous properties, it is difficult to inject it subctaincously in sufficiently small does, while it is not easy to obtain a solution in any meastrium in which decomposition will not take place. If a convenient method of disadving it could be devised, Ni(CO)₄ might become a valuable antipyrette, the median operation of which is intelligible.

SOCIETIES AND ACADEMIES.

Chemical Society, April a.-Mr. W. Crookes, FRS, Voce-Prendent, in the chair, --The following papers were read; and Citraconfluorescein, by J. T. Hewitt Lunge and Burchinave shown that maleu anhydride is capable of yielding a disportecion, the author has obtained the corresponding fluorescein. In earther his contraction of the contract fluorescent, the author has obtained the corresponding more rescent from citraconic anhydride, by the action of resortinol in the presence of sulphuric acid. Citraconfluorescent is easily soluble in alcohol and glacial acetic acid, fairly soluble in water, the aqueous solution is yellowish-brown and shows a green fluorescence — Ethylic thiacetacetate, by Dr. C. T Sprague Hubner obtained ethylic thiacetacetate by the action of sulphur Haber obtained eithylic thacetacease by the action of sulphur monocolloring. Secf., on enthylic accessedate. It has seen been monocolloring. Secf., on enthylic accessedate. The assess been eithylic accessestate, by Schunbrodt by the action of sulphur on the copper derivative of chipic accessenate, and by Michaelia and Fhilips from though chloride and eithylic accessestate, and by Michaelia and Fhilips from though chloride and eithylic accessestate, and the product accesses and the product of the composition of the accesses and the product of the internative formula, SQC C-CH (CQ,BL), was suggested by Delista. The author describes the preparation of the substance and the product of its interaction with hydramics; and shows that it behaves towards phenylhydrazine in the same manner as ethylic acciacetate. The results are in accordance with the formula proposed by Buchka.—The function of chlorine in acid chlorides as exemplified by sulphuryl chloride, by H E. Armchlorides at exemplined by sulphuryl chloride, by 11 E. Arm-strong A number of experiments carried out during recent years in the author's laboratory show that sulphuryl chloride, SQC/L, acts to hencenoid compounds simply as a chlorinating agent. Sulphuryl chloride is easily formed by the direct union of sulphur dixtude and chlorine in the presence of a catalyst, such as camphor, charcoal, or access cald, it is a highly mobile such as camphor, charcoal, or aceira said; at it is a highly mobile liquid of low boiling-point, and its steed on with extreme alow-ness by water and alkaline solutions. It is an meri substance of the point of the special activity, and is inclined to the wew that the activity of each chlorides is conditioned by the oxygen rather than the chlorine, this view being supported by the observations of Wagner and Saspiter, and the last one one of Paulow (Amalian, classivity 104). The sutton sales discusses the action of SQ_11C(1), and the analogous compound SQ_12C(1) and points out that pyromidplary chiloride, SQ_1C(1), behaves much as if it comisted of control of the the formation of a hright yellow derivative of lignone and pitrous acid On further interaction, large quantities of introus oxide, N_sO, are evolved, together with carbonic anhydride and a small proportion of nitric oxide A sensible quantity of hydrogen cyanide is also produced, the proportion being increased by increase of temperature. The observations point to the entrance of the NOH residue into the lignone molecule, its interaction with nitrous acid being finally the displacement of H, by O. The reaction is probably general for compounds containing the NOH residue, and the authors suggest that attention be paid to the gaseous products of the interaction of unitic acid and carbon compounds, as calculated to elucidate their mechanism.—The Chairman, Mr. Crookes, gave a short verbal account of observations on the volatilization of metals in vacuo under the influence of an electric discharge.

This investigation was carried on during last winter. It appears that M Hannoi made a communication of the subject to the Societé Chimique on February 97. He found the substance to be more poleopous than CO, and that the blood gave the spectrum of carbon-monoxide-hamnoglobin.

NO. 1125, VOL. 44]

April 16 .- Prof. A Crum Brown, F.R S , President, in the the chair.—The following papers were read.—Studies on the chair.—The following papers were read.—Studies on the chair.—The following caperns were read to the chair of the cha solution of diorthonitrophenol at ordinary temperatures, the normal product, namely parabromdiorthonitrophenol, is obtained However, if the mixture be hented at 100 for a short time. a mixture is obtained consisting of parabromdiorthonitrophenol and orthobromorthoparadinitrophenol. And if the heating be prolonged, and small quantities of bromine added, the mixed Prolonged, and small qualitates of bonning and an approached is converted into orthobromorthoparadintrophenol. Parabromdiorthonitrophenol is therefore completely converted by the action of heat, and bromine into the isomeric ortho-hromorthoparadinitrophenol. The same isomeric change takes place under the influence of nitric acid. An acetic acid solution of parabromdiorthonitrophenol, when heated with a few drops of orthobromorthoparadinitrophenol Experiments were then under taken with the corresponding chloro-compounds. It was found taken was nie corresponding chloro-compounds. It was found that chlorine had no action out dorthontrophenol when dissolved in acetic acid at 100°, even in the presence of todine Chlorination, however, takes place when chlorine is paved into a solution of dorthontrophenol in antimony pentachloride at 105°, and only the normal product parachloridintrophenol is formed Action of bromme on farachloridirethontrophenol—fixperiments to accertain whether twomers change could be effected. by the action of bromine on parachlordinitrophenol only gave negative re-ults, the normal product, parachlororthobromothonegative results, the normal product, paraconoromotoromotoromotoring introphenol, being obtained in every case. The author considerathat in the case of the chlorine compound homeric change does not take place, because the chlorine is more firmly held than browning action of sulphieric acid on orthogostalichtorphinal orthoutsplane and The combined action of heat and sulphieric acid on the combined action of heat and sulphieric acid. acid on orthoparadichlorphenoisulphonic acid gave no indication of any isomeric change taking place, although the reaction was investigated under a great variety of conditions of temperature, &c The corresponding dibromphenol also gave negative results, infection there is great variety of continuous or temperature, in the transverse data and the continuous or temperature of the transverse data and the continuous or the transverse of the transverse of the continuous or the conti that the Initial action in both cases is the same, but that the sulphate formed from orthonitrophenol as once undergoes isomeric change, whereas the sulphate from parantrophenol is more stable. The author did not succeed in obtaining any sulpho acid by heating the sulphate from the parantrophenol is a sulpho acid by heating the sulphate from the parantrophenol is a fair valid of the parantrophenol in the parantrophenol is a sulpho acid by heating at a com-half and or the parantrophenol is a com-half and the parantrophenol is a complete the parantrophenol is a com-half and the parantrophenol is a complete the parantrophenol is a complete the parantrophenol in the parantrophenol is a complete the parantrophenol is a complete the parantrophenol is a complete the parantrophenol in the parantrophenol in the parantrophenol is a complete the parantrophenol in the parantrophenol in the parantrophenol is a complete the parantrophenol in the paran at 100. But he outsimed a sizr yield of sulpsio acid by nearing the introphenol with two indecidar proportions of SO, [4Cl at 100" Hence, there is little doubt that the parantirophenol establishme acid is formed by the sulphonation of the sulphonate acid is formed by the sulphonation of the sulphonated Metantirophenol receibles the para compound in being converted also sulphate, but not hit to the sulpho-acid even by the action of the sulphonation of the sulphon verted mit sulphace, but not little vulpha-scall even by the action of heat.—Compounds of destrore with the oxides of nuclei, chromuns, and non, by A. C. Chapman, The nuclei compound is not being the proposal and continued by adding a solution of nucleic hydraie in a special more proposal substance, instabile in water and skeohol, of the composition $C_{\rm HI}/Q_0$ 2 May 0.9 + 3 H₀. The chromium compound, which appears to have the composition represented by the formula $C_{\rm HI}/Q_0$ 2 m/s, $C_{\rm HI}/Q_0$ is repeated by the formula $C_{\rm HI}/Q_0$ 2 m/s, $C_{\rm HI}/Q_0$ is repeated by the formula cells of $C_{\rm HI}/Q_0$ 2 m/s, $C_{\rm HI}/Q_0$ is repeated by the formula cells of $C_{\rm HI}/Q_0$ 2 m/s, $C_{\rm HI}/Q_0$ is repeated by the formula cells of $C_{\rm HI}/Q_0$ and $C_{\rm HI}/Q_0$ in the present of the composition into cold strong ammonia. The precipitated hydrid parily showled on standing, and so powing the purple solution to obtained mit to poper cells. Alphololy, the chromated destrowate a obtained as a historical collection of the composition of the compos coloured precipitate. The iron compound, 2C.H15Os.3Fe3Os

PAGE

+ 3H,O, is obtained by adding a slight excess of ammonis to a solution of ferric chloride containing an excess of destrose; on attaining, a deeper dolution so blanked, which when poured into 90 per cent. alcohol yields the destrosets of sroot as a red forculent precipitate. This most compound dissolve easily is decoulent precipitate. This most compound dissolve easily is decoulent the properties. The most is more decomposed by ammonis, potassic ferrocyanide, or potassic decomposed by ammonis, potassic ferrocyanide, or potassic decomposed by ammonis, potassic ferrocyanide, or potassic hidocyaniac. The day compound is unsoluble in water.—A rapid method of estimating principle of the reduction of intrict to Harrow. The method depends on the reduction of intrict to very dilute solution, in the presence of a nephthylamine and supplante acid; the estimation is made by comparing the depths of the past associations developed in the solution with that turing on similar restatents of standard nature solutions, artificial control of the solution of size dust, and due allowance is subsequently made. A number of comparisons with the manner prior to the addition of sue dust, and due allowance is subsequently made. A number of companisons with the Crum method show that very satisfactory results are obtainable. —The "gravitonimeter," an instrument by means of which the observed volume of a ningle gas gives directly; the weight of the gaz: a preliminary note, by F. R. Jepp, F. R.S. The suchor desertion as method of constructing a gas apparatus, by means of desertion as method of constructing a gas suparatus, by means of desertions a method of constructing a gas suparatus, by means of desertions a method of constructing a gas suparatus, by means of desertions a method of constructing a gas suparatus, by means of desertions a method of constructing a gas suparatus, by means of desertions are considered as a superatural desertion of the construction required single gas may, without observation of temperature or pressure and without calculation, be measured under such conditions that each cubic centimetre represents a milligram of the dinons that each cuiuc centimetre represents a milligram of the gas. The author describes the apparatus in deal and the method of sung it, and he saticipates that it will, at least, give most of the saticipates that it will, at least, give most of the saticipates that it will, at least, give most of the saticipates that it will, at least, give most of the saticipate of pressed by the following equations -

present by the following $_{2}C_{2}H_{2}NCS+6C_{5}H_{4}O_{5}=(C_{2}H_{5}NH)_{5}CO+3(C_{2}H_{5}O)_{5}O+2H_{2}S+CO_{5}$

 $(C_1H_1NII)_2CO + 2C_2H_4O_4 = 2C_4H_4NH_4 + (C_4H_2O)_2O + CO_4$ -The action of aluminium chloride on benzenold acid chlorides. by R. E Hughes, Jesus College, Oxford The author has ex-amined the action of aluminium chloride on connamic and hydrocinnamic chlorides, in the expectation that pentamethylene derivatives might result. The experiments, however, afforded negative results. The chloride was either dissolved in or mixed with light petroleum, and aluminium chloride then added; action set in at 80-90° in the case of cinnamie, and at 50° and more briskly in the case of hydrocinnamic, chloride The chief product in both named case of nyarocanamic, caloride the cases was an ill-characterized substance, which has not been examined. The author also describes the following compounds: hydrocanamic chloride, hydrocanamide, and hydrocinnam nydrocinname entorice, pydrocinnamide, and nydrocinnami anillide. It is noted that benzoic and eninamie acids may be readily separated by treating the mixture with phosphorus pentachloride and distilling the product under reduced pressure; the portion passing over below 95' under 10 mm, contains the benzoic chloride

MEDICAL RESEARCH AT EDINBURGH Laboratory Reports of the Royal College of Physicians of

Edinburgh, Vol III (Edinburgh and London Young J. Pentland, 1891)

OW that for three years the laboratory of the Edinburgh Royal College of Physicians has shown steady advancement in every direction-in the number of workers engaged within it, in the volume of work accomplished, and more especially in the quality of that work-Dr Grainger Stewart and his Council must congratulate themselves heartily that they were undeterred by any misgivings from entering upon a venture which has been so abundantly successful, and which has added so much to the renown of the College. It must be a source of very sincere satisfaction to them, and especially to Dr Batty Tuke, the prime mover in its organization, to know that no laboratory in the Kingdom can show for the same space of time a record of so much good work in so many directions, of which a large part would never have been undertaken had this laboratory not been established

In many respects the present volume exhibits marked improvement as compared with its predecessors. While composed of more than a dozen papers, these only represent but a portion of the investigations that have been completed, and all of them contain matter of permanent interest, others whose interest is of a more temporary nature have, I think wisely, been excluded The value of the volume is further enhanced greatly by the fact that the majority of the reports appear here for the first time Among these may be mentioned Dr. Helme's important contribution to the physiology of the uterus, Di Gulland's heterodox papers upon leucocytes and adenoid tissue: Noel Paton and Balfour's very full studies upon the composition and physiological action of the human bile; Woodhead and Cartwright Wood's observations upon bacterio-therapeutics; and a short but important communication by Cartwright Wood and Maxwell Ross on the influence which the process of inflammation exerts upon the course of infectious disease Taking these in order, Dr Helme's paper is of especial

value, not only clinically, from the light it throws on the mode by which certain drugs act upon the uterus, and from the consequent indications it affords as to the conditions under which they may wisely be administered, but also as a contribution to the physiology of non-striped voluntary muscle. Employing the uberlebende organ the organ removed with all precautions immediately after the death of the animal (a sheep)-and continuing the circulation through it artificially, Dr. Helme has been able to study its slow rhythmic contractions apart from the influence of the central nervous system and of the changes in the blood supply From a physiological point of view, his most important observation is perhaps that which brings out the striking difference existing between striped and non-striped muscle as regards the relationship between contraction and blood supply striped muscle during contraction becomes hyperæmic, the uterus, the largest mass of unstriped muscle in the body, becomes during contraction relatively anæmic.

It is impossible to pass Dr. Gulland's articles upon the nature and varieties of leucocytes and upon the development of adenoid tissue without bestowing on them not a little adverse criticism, and this, while appreciating fully the long months spent in laborious preparation and examination of tissues, and in studying the literature of the subject, of which they bear ample witness. That Dr Gulland bases his conclusions upon the view that the leucocytes are symbiotic, and shows at the outset that he totally misconceives the nature of symbiosis, is quite sufficient to render fuller criticism of his views unnecessarv Yet, that it may not be said that I misrepresent his views, it may be as well to quote his words upon this súbiect ·-

"There are still" (in the Metazoan) "many functions to be performed which can only be discharged by cells possessed of Protozoan characteristics. these functions it is necessary that a certain number of cells should continue to be practically Protozoa, and these cells are what we call 'leucocytes,' so that we may regard them morphologically as representing those members of the primitive Metazoan colony which escaped differentiation, and have remained unaltered Protozoa through the whole series of Afetazoa" (the Italics are mine)

Such inconsequent theorizing goes far to neutralize the minute and careful observations which Dr. Gulland has

made into the histology of his subject

That the formation of hile solids is more closely associated with the general metabolism than with the changes of digestion is the conclusion drawn by Dr. Noel Paton and Mr Balfour, though somewhat unexpectedly they find that in fever, where the general metabolism is greatly increased and the digestive processes reduced. the amount of bile solids excreted is diminished studies of cases of biliary fistula in man are of value, and such full observations as those here described are rare Of drugs they find calomel and salicylate of soda active in increasing the flow of bile. Whether they are right in looking upon the bile as an excretion, rather than as at the same time a secretion playing an essential part in digestion, is open to doubt Even if with bile excluded from the intestine only 30 per cent of the fats ingested pass out unused that nevertheless is a proportion large enough to demand consideration, and to support the assumption that as a secretion, as well as an excretion, the bile is of definite importance The ingenious method devised for the estimation of the bile pigments (p. 197) deserves a more extended trial.

At a time when Koch's endeavours to cure tuberculosis by means of injections of products of growth of the tubercle bacilli have brought the whole subject of bacteriotherapeutics prominently to the fore, the full discussion of this by Drs Woodhead and Wood is very acceptable, based, as it is, upon their own important discovery that the invasion of the organism by the bacillus of anthrax may be prevented by injections of the sterilized fluid in which the Bacellus pyocyaneus has been grown. Space forbids that I should do more than indicate that those interested will here find a full account of our present knowledge of a subject which is occupying the energies of every leading bacteriologist

Of allied interest is the communication by Dr. Wood and Mr. Ross. It has long been known that the advance of erysipelas can often be successfully combated by panting the skin immediately outside the crysipelatous area with some counter-irratant. The authors have studied the rationale of this treatment, and conclude that the Irritant berniga about the formation of a tone of inflammation, with dilatation of the vessels and dispedess of the white corpuscles, which now, by destroying the micrococca, act as a barrier to the further progress of the disease. With the malignant pattle produced by the inoculation of the anthras bacilli, similar counter-irritation was effectual in only three out of thry cases—that is to say, with the more active virus the stimulus applied was not sufficient to produce an effectual barrier. J GEORGE ADAM.

THE CHEMICAL AND BACTERIOLOGICAL EXAMINATION OF POTABLE WATERS.

Examen Químico y Bacteriológico de las Aquas Potables Por A E. Salazar y C Newman, con uno capitulo del Dr. Rafael Blanchard sobre "Los Animales Parásitos introducidos por el Aqua en el Organismo." (London · Burns and Oates, 1890)

PECULIAR interest attaches to this work at the present moment in consequence of the sad political events now going on in the country from which it has emanated; for, whilst almost each successive day brings news of the sacrifice of human life in one of the fiercest and most sanguinary civil contests of recent years, the object of this book is to show how the latest results of scientific research may be applied to combating on the same soil some of the ills which flesh is heir to. The publication of this treatise for Chilian students affords the strongest evidence of the rapidity with which scientific knowledge traverses the globe at the present day, and it must be a source of great satisfaction to all interested in the dissemination of the principles of hygiene that there should be a demand for a work of such an advanced character in a country so remote from what we are wont to regard as the centres of civilization

The scope of this work is more comprehensive than that of perhaps any similar one in our own language: English treatises on water analysis being in general only short manuals giving instructions for the execution of analytical methods devised by their authors, who usually dismiss the rival methods of others with a few words, often not of a very complimentary kind The pages under review, however, not only give an interesting account of the various methods employed by water-analysts, but subject their several claims to a fair and impartial criticism, whilst detailed information is supplied for carrying out those methods which the authors regard as, on the whole, the most serviceable. Again, a most exhaustive account is given of the bacteriological examination of water, including precise instructions for the cultivation of micro-organisms, the preparation of nutritive media, the sterilization of apparatus, the use of the microscope, and the performance of inoculation experiments on animals. But even this ample programme was inadequate for the ambition of the authors, who have associated with themselves a third colleague, who contributes a bulky appendix on "the animal parasites gaining access to the organism through water." The work is not only profusely illustrated with cuts, but contains also a number of ori-

ginal photographs representing both the microscopic and macroscopic appearance of some bacteria. Indeed, the bacteriological part is the real centre of gravity of the work. A decade will soon have elapsed since the bacteriological examination of waters began to attract much attention in consequence of the ingenious method o gelatin-plate cultivation devised by Koch It was not, however, until some years later that the method yielded results of any practical importance, masmuch as it was at first almost exclusively applied by bacteriologists whose previous information on questions of water-supply was of a somewhat limited order, whilst the value of the method for the solution of many hitherto unsolved problems connected with the hygiene of water is even now but imperfectly appreciated by chemists. When the method was first applied to the London water-supply, in the year 1885, it at once brought to light that in the process of sand-filtration, as practised on the large scale, a most astonishing proportion of the micro-organisms present in the unfiltered water were removed, whilst in the best of our deep-well waters the number of microbes found was so small that it seemed probable that the removal of these low forms of life in this process of natural filtration was really complete, and that the few actually found had very likely been imported into the wells from the surface On the other hand, it was shown that the sand-filters did not wholly remove the organisms present in the unfiltered water, as, in the course of regular examinations carried on over a period of more than three years, a most unmistakable relationship between the number of microbes present in the unfiltered and filtered waters respectively was discernible. The scope of the bacteriological method of examination became very much narrowed when it was discovered that there are many micro-organisms which have the power of multiplying to an enormous extent in the purest waters, including distilled water itself, so that the number of inicrobes present in a given sample of water affords no indication per se of the purity or otherwise of the water. This disturbing element in the bacterioscopic examination of water is not sufficiently emphasized by the authors. But this extraordinary phenomenon of multiplication, although it invalidates the bacteriological process for the general purposes of water examination, does not at all interfere with its successful application to the investigation of the efficiency of filtration, either natural or artificial, provided that the filtered water is subjected to examination without delay after it has undergone the process of filtration

It should be pointed out that there exists a very widespread misapprehension as to the ideal object of the bacteriological examination of waters, and the authors of this work fail into the same error to some extent also. It is very generally supposed that the main object of a bacteriological examination is to discover whether or not there are disease-producing organisms, e.g. those of typhoid, in the water. But this is a point really of very limited importance, and what should be kept in view in an examination of water is the endeavour to discover, not whether the water contains symotic poison at the time of analysis, but firstly, whether it is exposed to influences which may at any time lead to the introduction of such symotic poisons, e.g. through contamination with swange; and secondly, whether, if such organized poisons should gain access, there is any sufficient guarantee or not that they will be destroyed or removed before the water reaches the consumer. It is because the chemical analysis affords us at present a better clue than the bacteriological examination as to whether a water has received sewage or not that it is of more general applicability than the latter; but we must appeal to a bacteriological inquiry in order to ascertain whether, in the event of sewage gaining access to the water, there is a guarantee in the subsequent history of the water that the zymotic poisons, which may at any time accompany the sewage, would undergo removal In short, the object of nearly all water examinations is obviously to ascertain whether the water may at any time be dangerous to health, and not, even if this could be with certainty determined, whether it contains a zymotic poison at the particular moment of examination. On the other hand, the fact that the microbe, which is now pretty generally accepted as the inducing cause of typhoid fever, has been on more than one occasion actually discovered in drinking-water which was under suspicion of producing an epidemic of that disease, affords most important evidence as to the manner of its distribution

There is much need of a similar work to this in English, as each year an increasing number of younger medical men are coming forward for the degrees in Public Health which are now granted by several of our Universities, and to these a practical and critical treatise such as this would prove of great value It is of great importance that such Public Health students should be impressed with a sense of the responsibility which attaches to the examination of waters for domestic purposes, and that most serious mischief may and often does result from such investigations being intrusted to incompetent persons. It is gratifying to see that the authors do not undertake to prescribe any of those artificial standards of purity for drinking-water which so frequently figure in books of this kind, and which are attended with the greatest danger, leading as they do the ignorant to believe that they can pronounce upon the fitness or otherwise of water for drinking purposes from the numbers which they have obtained in a few simple quantitative determinations For it must never be forgotten that the sanitary examination of water is surrounded with such difficulties that it is only by bringing to bear on each particular case all the evidence that it is possible to obtain, and then interpreting this evidence by the light of an extended experience, that a sound judgment can be arrived at P F. F

OUR BOOK SHELF.

Botany a Concise Manual for Students of Medicine and Science. By Alex Johnstone, F.G.S. (Edinburgh and London: Young J. Pentland, 1891.)

DURINO recent years many books on botany have been published, specially for the use of students preparing for examinations. In these a few types and phases of plant life have been described somewhat in detail. In the present case a much wider range has been taken, the result being an illustrated botancial note-book, condensed but not meagre. In the preface the author takes it for granted that every student nowadays attehis fectures

or demonstrations, and "therefore does not so much require a manual with diffuse explanations, but rather a kind of illustrated digest and general note-book, which will enable him to quickly arrange and make most effective use of the various facts and set of the various secessful in producing It consists of 260 pages and 2:56 illustrations. Some of the latter are the ones which seem by cates to the considered necessary for reproduction in every fresh abouncal manual, white others appear to be refresh boancal manual, white others appear to be represented by the second of the second section of the producing of cells, give a much clearer idea than could be done by pages of letterpress. A short introductory chapter points out the position boansy holds in science. The strictly botanical part of the work is treated of in or veranoratiny. (1) physiology, and (6) laxonomy

consequency and the consequency of the general consequency of the cons

The arrangement throughout the book is good The various headings, &c, printed in type differing according to their importance, have been very carefully set out, and give a good resumé of botany in a tabular form As an illustrated note-book for a teacher, as well as a student, this work will be found of great use C H W.

Hand-book of the Ferns of Kaffraria. By T R Sim, Curator of the Botanic Garden, King Williamstown, South Africa 66 pages, 63 plates (Aberdeen Taylor and Henderson, 1891.)

THI's little book contains popular descriptions and outline plates of the ferms of Kaffrain, with a chapter of definitions of the botanical terms used in describing ferns, and another giving directions how to cultivate them. The Cape, considering the general interest and remarkable of the plantened of the control of the plantened of the control of the plantened of the control of

recognizing any of the Kaffrarian species; and perhaps at some future time Mr Sim, who was trained at Kew, will extend his area so as to cover the whole colony, for which the total number of ferns known is between 130 and 140,

Rider Papers on Euclid. Books 1.-11 Deakin. M.A (London: Macmillan and Co. 1891) THIS little book consists of a series of graduated riders so arranged that the beginner may be able to thoroughly understand and grasp the principal propositions of the first two books of Euclid. One of the chief errors that the -author endeavours to avoid is the great stress teachers lay on some of the propositions, which are treated as

most important, while others are more or less overlooked The method he adopts is to treat each proposition first as a rider, and by giving the enunciation and drawing the figure, see if any of the class can show how it is proved By this means the subject can be made interesting, as beginners can then look upon each rather as a puzzle than

as a stiff piece of work

The two books are divided into nine parts, each part consisting of six papers, and the riders in each paper, with the exception, of course, of the first, deal with all the preceding propositions. The student is advised in the first six papers only to draw the figures, in order to accustom himself to one of the chief difficulties which, as the author says, "experience shows me that all students feel more or less in solving riders."

At the end are printed the enunciations of the propositions of the two books, followed by several papers set at various examinations Altogether, teachers will find this an admirable help for classes in which the subject is

Die Krystallanalyse oder die chemische Analyse durch Beobachtung der Krystallbildung mit Hulfe des Mikraskops mit theilwaser Benutzung seines Buches uber Molekularphysik Bearbeitet von Dr O Lehmann (Letpzig Engelmann, 1801)

WE have so recently noticed at length the splendid work of Dr O. Lehmann on "Molecular Physics" (see NATURE, vol xlii p I) that it is only necessary in this place to call attention to this pamphlet of 82 pages, illustrated by 73 woodcuts, in which the author gives the necessary directions for the work of micro-chemical analysis The instruments used and methods employed are concisely stated, and all the essential details of the operations are supplied to the chemist in this little handbook Dr Lehmann claims, not unjustly, that the methods of micro-chemical analysis must play the same part in the laboratory of the organic chemist as spectral analysis does in the laboratory of the inorganic chemist

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Nisther can he undertake to return, or to correspond with the worsters of, rejected manuscripts intended for this or any other part of NATURE. No nistice is taken of anonymous communication:

The University of London

My friend, Mr. Thiselton Dyer, invites me, by his references My frend, Mr. Thuelton Dyer, avates me, by haveferences to what I have written on this subject, to a discussion in your columns. I am very unwilling to accept the invitation, because I have already and done stated my verse, and because I see by have already and the state of the

would rescue from proverbial oblivion the pages of careful state-ment entombed in a Blue-book. Since, however, my friend trails his coat, it would be doing violence to my old-established regard

for him to refuse to tread on it—just a little

The question raised by Mr Dyer seems to be, why should not
the examining board in Burlington Gardens undergo certain reforms and continue to be the so-called University of London? It has done good service to education, he says, and with the removal of more than half its members and their replacement removal of more than half its members and their replacement by gentlemen who either really know or really care about University education it might do more. If it were, he suggests, to rise superior to all its most solemn obligations and faisily the pledges of its founders by undertaking to teach as well as to examine, it would really be as much of a "teaching University". examine, It would reary be a final of a teaching a set set ther Oxford or Cambridge, and its non collegiate supporters from all parts of Britain might enjoy the spectacle of the mother-college (University College) from which this examining

mother-college (Unwently College) from which his examining board took birth, shandoning in favour of Burington Gardens those traditions of accentific research which have made the College is some measure a tealitation of Fichte's deal.

[Mr Typer seems to have forgotten the facts when he contends that such teaching as Fichie sketched in his plan for the University of Berlin, cannot be arried on in the same institution. or by the same men who administer the teaching required by a or by the same men who administer the teaching required by a University valued at the commencenneil offsite career. Fichtie's plan was carried out in the University of Berlin, and has been followed by every other University in Germany. The very questions which we are now debating were debated in the early categories. The commence of the commence of the commence of categories which we are now debating were debated in the early categories. The commence of the commence of categories which were contributed to founded (except so far as it was a private enterprise) on the function of a German University, and only required the working and founded (except so in as it was a private enterprise; on the intens of a German University, and only required the privileg and independence conferred by the power of granting University degrees to enable it to fulfil in London Fiche's ideal. Its professors have never been (as Mr Dyer well knows) mere in structors for examination purposes. The researches of Craham, tendro of never need name of the week of the con-lement of the control of the co in Burlington Gardens, on the ground that it is inconsistent with the teaching of University undergraduates, appears to me to involve an erroneous conception of what University education and University organization should be This by way of parenthesis?] The point which I wish to insist on is that, excepting the pro-

posal to undertake higher professorial teaching, I have no objection whatever to the reforms of the examining body in Builington Gardens advocated by Mr. Dyer

What I desire (and I merely use the first person singular for the purpose of discussion, and not because I stand alone in my wishes, or undervalue the support of others) is that, without any of granting degrees should be coaferred by the Crown upon a combined Senate consisting of the Professors of University and King's Colleges (the authority of the councils of the two Colleges

being duly guarded)
The fact that Burlington Gardens are in London and that University and King's College are also in London, as well as the talk about a teaching University "in and for" London, have very little bearing upon the question as to whether it is or is not very little bearing upon the questions as to whether it is or a not desirable to grant. University privilege to the two Colleges. There is population enough and accommodation enough for a state to judge as to the primaples which should quide the Crown in bestowing the privilege of incorporation as a University, the only questions to be saked are "Does the body which asks for only questions to be saked are "Does the body which asks for personal properties of the privilege of incorporation as University, the particular that the properties of the pr now and hereafter? Will the concession to them of this privinow and hereafter? Will the concession to them of this privi-lege tend dructly or indirectly or both to the public welfare?" I cannot imagine that anyone will undertake to give a negative University and Kingh. "Certain it is that during the courte dis-cussion which has been carried on for the last four or five years, no one has wentured to do so. What has happened it simply this, that persons connected with Burlington Gardiens have opposed the between of University powers on the two Colleges, either for the reason that they consider the withdrawal of the either for the reason that they consider the windrawai or the Colleges from the sphere of the operations of the Burlington Gardens examining board a reflection upon that body, or be-cause they are unwilling that a privilege should be conceded to Colleges, however well fitted to receive it, which their own local or provincial college is not yet important enough to claim. A further incident of the movement has been that the just demands of London medical students and their teachers for a University degree in medicine, as readily attainable by London students as are the medical degrees of Fdinburgh, Glasgow, Dublin, Aberdeen, St. Andrews, Durham, and Cambridge, by the students

Neither of these accompaninents of the request for University
powers made by University and King's Colleges seems to me to touch the question as to whether it is right on grounds of public policy to accede to that request. Sir William Thomson, Sir George Stokes, and Mr Weldon after an exhaustive inquiry George Stokes, and Mr Weidon after an exhaustive inspury were in favour of granting the privitige skeld for Three lawyers, namely Lord Sebborne, str James Hannen, and Str James Ball, were not persuaded. The commission composed of these six genilemen agreed to ask the Burlington Gardens authorities to try to devire such alterations in their "University" as would satisfy the aspirations of University and Aings, Colleges Burlington Gardens has absolutely and hopplessly of the problem could foresee must be the case. They have They have proposed a scheme which has not been accepted by the Colleges. and has also been rejected by their own provincial graduates.

Why should more time be wasted about the attempt to put
three pints into a quart bottle? Let the Burlington Gardens University continue to exercise its function of examining for schools and colleges which are not strong enough to examine schools and colleges which are not strong enough to examine for themselves, and let them continue so to do only until the colleges are fit to receive independent University powers, let the Senate reform itself if it can, and if the shurd dead-weight of graduates itted round its neck and called Convocation will of grautates tied round its neck and cause Convocation will permit it to do so. But do let us have in the meanwhile a genuine professorial University set on foot in London, not because it is London, hut because University and King's Colleges are there, and respectfully petition Her Majesty to do for them what the monarch has done (not unwisely, it must be allowed) in past days for the Senatus Academicus of Edinburgh, of Aberdeen, of Leyden, of Beilin, Bonn, Leipzig, and other

What the two Colleges ask for is a privilege—a special favoir To include other institutions as co recipients of the privilege To include other institutions as co recipients of the privace would destroy its character and its value. As Mr. Dyer points out, we do not want a federal University, such as are Cambridge and Oxford and the Victoria. We have seen enough of the and Oxford and the Victoria. We have seen enough of un-frietion and never-ending committees and schedules of such climatily organized Universities. By limiting the charter to University and King's Colleges, a professorial University can be established in which the professors shall be—as in the Scotch established in which the professors shall be—as in the South and the German Universities—a once the teachers, the examiners, and the governing body. I cannot persure what great manners, and the governing body. I cannot persure what great persure the control of the persure that great persure the grea acquire importance by their interface proposity conducting the affairs of the committees and boards in which what is good and strong in each member is counteracted, whilst only le, worthless, and emasculate survive-

The professorial University formed by a union of King's and University would be of modest dimensions, and rightly so. It University would be of monest dimensions, and rightly so, at would in vittee of its charter be able to grow. This I regard as the most important feature in the proposal. Instead of hastily bringing together a variety of teaching bodies, we should leave it to the new University to assimilate them, make terms with them, in the course of time.

them, in the course of time. Though they are modest bodies compared with the Imperial serial Impulsion and the Impulsion of which they seek to be a standing the protein of the Impulsion of which they seek to seating the property and the number of students which they would bring to the new University, which are far larger than the corresponding figures for many other Universities both in the United Kingdom and abroad. Their buildings and land are worth had a sufflion string. Their annual receipt access (2,0,0,000, their 1 sufflion strings. Their annual receipt access (2,0,0,000, their 1 sufflion strings.)

annual attendance of students is as great as that of the University of Oxford. This is an ample basis; with this start the new University would without any doubt be able to ensure a steady

Ufferently would without and doubt be able to ensure a steady growth, increase of its properly seek is teaching capacities, by a healthy and gradual development.

Mr Dyer skildly seek to enlish support for the supremacy of Barlington Gardens by asking the following questions (of which he does not give the answers for obvious reasons) "Why should two out of many institutions be picked out for University honours? Why should Beeford College be left out? How can the Royal College of Scence he ignored? Why ignore the City and Guilds Institute?"

These questions are excisable only when we admit that Mr Dyer may for the nonce treat his defence of Burlington Gardenas a lawyer may treat a shady case entrusted to his advocacy in the courts

The reason why the Crown should pick out the two Colleges The reason why the Crown should pick out the two Colleges for the University privilege; is, firstly, that they and they alone have asked for it, secondly, that they and they alone possess the property, professoriate, states, and historical purpose which could warrant the privilege; and, lastly, that University powers are essentially a privilege fitted and intended to strengthen and are essentially a privilege fitted and intended to strengthen and build up the institution to which they are granted above others leditord College is cared by Mr. Dyer solely, I am afraid, with the purpose of rooting the jestowy of its members. They are, they are the purpose of the purpose of the purpose of the con-traction of the purpose of the purpose of the purpose of the state of the purpose of the purpose of the purpose of the purpose portance to University and King's. As to the Royal College of Science, the answer is different. It is a Government institution under a upscal department founded and current on with a special under a special department tounded and carries on wins a special paperose. It grams its own certificates and fulfills is objects a special paperose of the paperose of the paperose of the carries of the It grants its own certificates and fulfils its objects exercised by Burlington Gardens.

The fact appears to me to be that centralization in University matters is wasteful of time and energy, paralyzing and delianve Two Colleges like University and King's can unite and settle their affain together, and if granted such powers as other Universities possess they may in time take into their organization, partially or completely, other institutions, or arrange methods of co-operation with other institutions. Indeed they would, if incorporated as a University, be sure to do this, and to do it far more efficiently than could be the case were they shrupily associated with a variety of rival corporations, each with equa-rights and equal voice, and left to compromise and to vote through endless committees, either as constituents of a reformed Burlington Gardens University or of a new piece of federal

Burlington Gardens University or of a new piece of resues. Mr. Dyer has swelpt awoude the question of the demand for medical degrees. I confess that this is a very difficult problem on account of the attitude of the medical profession. If the medical profession if the health of the profession is to be allowed to grain medical degrees. On the profession is the allowed to grain medical degrees, the profession is the profession of the medical profession is the profession of the medical profession is the profession of the medical profession in the matter. The thing to be attend at a for remedy medical profession in this matter. The thing to be attend at a for remedy an injustice; it is necessary to provide a degree as accessible as that of other Universities through whatever University or Uni-versities may exist, hereafter, in London.

In my evidence to the Commissioners I made some sugges-tions on this matter. I am inclined to think that the following steps are necessary for a satisfactory solution of the problem (a) the abolition of the medical faculties of University and

King's Colleges—excepting the Professorships of Anatomy, Physiology, Pathology, and Forensic Medicine—and the crea-tion of independent clinical schools attached to the North London and Lincoln's Inn Hospitals; (6) the nomination of a London and Lincoln's Inn Hospitals; (*) the nomination of a medical professoriate for the new University by representatives medical professoriate for the new University by representatives filled up on the recommendation of the Senate of the University, (*) the recognition, under conditions, by the new University, of the clinical teaching in each of the London bospitals, and the admission of students to its medical degrees on conditions. tion of having passed the prescribed examinations of the University and of having pursued not necessarily more than one-half of the entire curriculum under the professors of the University. The University might also be required to re-University. The University might also be required to recognize (in exchange for a like concession) the examinations
in certain subjects of the Conjoint Board as excusing candidates
from like examination by the University.

This is undeniably a complex part of the subject. It would

be simplest, and probably satisfactory in the end, to grant the nower of giving medical degrees to the limited body (King's and University) and to leave it to make such arrangements as it might find expedient with the medical schools of London. The professional feeling of the medical faculties of University and King's Colleges would insure their making an equitable use of the privilege, such as their medical brethren would heartily approve.

E. RAY LANKESTER.

approve.

or super advanced as an argument in favour of external or superior examining boarts in University examinations as opposed to examinations conducted by University professors with associated external examiners. Mr. Dyer has, however, omitted to cite the reply which I had siready given to his specious argument, the contract of the reply which I had siready given to his specious argument, which is the simple size of the reply which I had siready given to his specious argument, which is the size of the size work of the Senate of Burlington Cardens. Eather University professors are workly to occupy their positions or they are notion bigher branch of the educational profession exists. To correct them by means of Senates composed of retired teachers and distinct of Senates composed of retired teachers and distinct of the control of the cont

If we are to have an intensite series of authorities one above the other, who, one would like to know, is to control the examining board which sits over the professors? And who

again to control these controllers?

The bureaucratic machinery which seems to find favour with Mr. Dyer is, in my opinion, superfluous The most efficient Universities (in two differing directions), those of Germany and of Scotland, have no authority in educational matters above that of the professoriate, and are not subject, like Oxford, Cambridge, and London, to the interference of graduates in the form of convocation

MR. THISELTON DYER appears to think that Fichte's ideal of a University is unrealizable, unless, as he supposes, "some wealthy man gives, say, half a million to found such a University in some quiet country town in England, where professor and

pupils might labour together, andisturbed by the life and movement of a big city, or the worry of the examination-room, for the advantage of knowledge." I venture to think that this sup-position of Mr. Thiselton Dyer's conveys the unwelcome truth position of Mr. Thueston Dyer's conveys the unwescome transitatine conception of the true nature of a University has not yet reached some even of that section of the British public who have earned well-merited distinction in science, and it is as one of the control of the Scottleh and a German University, have earned wein-merited distinction in science, main a is as one who has had experience of a Scottish and a German University, in the character of student and teacher, and of two English University Colleges as teacher, that I ask permission as abortly as I can to place before your readers what many minds aim at, in the hope that a teaching University in London, call it what you will, would ultimately provide it.

I resterate the assertion which I jately made in a letter to the

I reterate the assertion which I lately made in a letter to the Timet, that a University is primarily a place for the extension of the bounds of knowledge, this is to be achieved by the labours of the professors and teaching staff; by fellows, specially appointed for that purpose, if the system of fellowships is thought desirable, although, in my opinion and experience, much may be said against it, and by the whole body of the students. Of course is not to be supposed that every student students. is capable of discovering new facts or of applying principles in an original manner, but almost every man is endowed with some share of inventive faculty, which must ultimately be developed. if he is to make his way in the world otherwise than as a daylabourer, or as a piece-worker in a factory, or as a copying-clerk; and the object of a University should be to cultivate this cierk; and the object of a University should be to cultivate this faculty to the utmost. An efficient medical man spends his life in clinical experimentation; a successful barrister exercises his ingenuity in applying old decisions to new cases, a competent engineer not merely studies how to improve his machinery, but also studies his fellow-creatures, and the chances of trade, so as faculty is not developed at the University, it will be developed later, in every man who fulfils his duty to his fellow-creatures and to himself.

and to numseii,
Now I dare to contend that the degree-stamp of the English
Universities, especially of the University of London, except in
certain cases in its highest degrees, such as the D.Mus, D.Litt,
M D, and D Sc degrees (and these only as a result of recent
modifications), is of no value whatever in the eyes of that modifications), is of no value whatever in the eyes of that portion of the public whose opinion carries with it a commercial reward. Speaking for mysell, I have had assistants, graduates of Edinburgh, of London, and of German Universities, and I unhe-statingly state that the only degrees to which I should attach the leax importance are those of Germany, and that because there is in them some evidence that the graduate has had. as least an initiation into the methods of research. As this assertion may be applied personally, I should wish it to be clearly understood that I have no reason whetever to be in any way dissatisfied with graduates from Edinburgh or from London, way disastisfied with graduates from Edinburgh or irom London, that merely to take that the fact of their being graduates in no way influenced me in their appointment. And many manifecturers, in want of assistants, actually regard an English degree in the light of a disqualification, so that most of the posits of "works-themists" are held by non-graduates. They prefer, in fact, to train their own men—that is, to give them such an education in research as hears on the particular problems which they themselves have to solve, or to take them from the laboratories of general analysts, where new problems present themselves from time to time,

themselves from time to time.

It is suppossible, under existing circumstances, to give underIt is unjoachie, under existing circumstances, to give underThey judge from the standpoint of "Will this 'pay' at an
amaniance?" And they cannot be blained it is not the fault of
knowing?" And they cannot be blained it is not the fault of

the standard o value, except in the eyes of school teach hers. Personally I canvalue, except in the eyes of school teachers. Fernonally I call-not complain that I do not get research done by students; in sextual fact a considerable number do stay after graduation, and some do not graduate at all. I merely hold the opinion that the method is on wholly wrong lines; that a degree, if given, should be the official testumory to a certast time speat with diligence and profit in guning knowledge useful for the purpose in-problems—of how to equite knowledge useful for the purpose in-

It will be said that honours-degrees will find no place in such

a system. Why should they? Does the desire to beat com-

position stimulate a desire for knowledge? Does it stimulate originality? I to one would willingly set them non-exament. Up to a certain point, the acquisition of knowledge of facts should be, as at present, tested by examination, but I saw convinced that the system is at present pushed to an extreme, and the state of the state ciently qualified.

It may also be said that undue advantage would be taken by the teacher in recommending unfit students for graduation. Teachers in such positions are, I believe, generally honourable men; they are chosen after the most careful inquiry into their past career It is not held fitting in commercial circles to appoint a clerk or an accountant on good recommendations, and after sufficient apprenticeship, and then to surround him with safeguards, in case he turn out incapable or dishonest

The objection may possibly be raised, that under such a system the standard of degrees would be very uneven, but what of that? As at present, anyone applying for a post of any kind would furnish a reference to his teachers, and a private letter from one well acquainted with the candidate turns the scale, for or against, in spite of every degree in the United

In plain English, degrees, as at present given, are not valued by that portion of the public qualified to judge, and we must face this fact, and endeavour to render a degree a real mark of

I believe, with Mr Dickins, that the examinations of the University of London have done much in disseminating knowtedge, and they have therefore proved of great service, but fedge, and they have therefore proved of great service, but except in the case of the higher degrees before mentioned, and of the degrees in the Faculty of Medicine where evidence of training is a new yell sond. I greatly doubt whether they have contributed towards the creation of knowledge, or training in originality And from the very nature of the constitution of the University of London, it is impossible that it should be otherwise. This of Lobiust, it is impossione that it is notwed by clearure were morning. I happened to ask a student attending my lectures on organic chemistry why he, a B. Sc. in chemistry, was attending my lectures. His reply was characteristic: "I scamped up enough of the subject privately, in; to squeeze through, hu mow I wish to know it." In any right systems, such a proceeding

should be impossible

It is therefore with the hope that the creation of a teaching University for London might tend to remedy such evils, that I University for London might tend to remedy such evils, inat 1, for one, would welcome it. I would urge that the distinguished names mentioned by Mr. Thiselon Dyer are surely guarantees that the London Colleges recently possessed men capable of imparting the highest standard of knowledge, and of stimulating true originality, yet I believe that it is by no means "cutting cheese with a razor" to employ just such men in watching over the development even of junior students; and it is not without advantage to the most able men of science and of letters to be obliged periodically to devote consideration to "elements" to pass in review first principles. It counteracts the tendency towards specialization, which, however valuable, always limits the mental horizon. I will undertake to say that the quality of the most divined tesching in blookgy and physiology in the control of to pass in review first principles. It counteracts the tendency well be shared by assistants, in order that the professor may have time to devote to research, and to superintendence of advanced students, it would be a serious calamity were the influence of such minds to be withdrawn wholly from the juniors

it is precisely by such a federation of Colleges such as University and King's, and of other sufficiently qualified institutions which have the will and the power to join, that specialization may altimately be effected. The fature occupants

of the chairs may be chosen so as to represent every side of a subject; and anyone wishing to pursue research in any special branch would have no difficulty in selecting that particular college where his specialty was also the specialty of the teacher.

WILLIAM RAMSAY

No well wisher of the University can feel otherwise than no well waner of the University can teel otherwise than grateful to you for affording a portion of your valuable space for the letters of Mr Thiselton Dyer and Mr Dickins on this subject. No two men could be found to speak with greater authority from first-hand knowledge of the facts. The arguments on the ject. No two men could be found to speak with greater authority from first-hand knowledge of the facts. The arguments on the subject have been too much of an exparte character hitherto, not setdom based on insufficient mformation or erroneous impressions. Nothing, for example, could be further from the truth than the statement in the *limes* of May 13, by the writer of what was

upon the whole a fair and comprehensive leading article, that 'there is no reason why the highest honours of the University of London should not be obtained by a person who never set foot in London or even in England "Many, who like myself foot in London or even in England "Many, who like myself voted for the projected scheme of the Senate, must have felt, as I did, as a result of a wide and varied educational experience, that it was potential with great good in the future, and could be ac-University, although we felt that the one serious blot in it was the abandonment of uniformity in the examinations for the pass degrees. I verily believe that this was the one thing fatal to its success in Convocation, that it was so far in excess of the recommendations of the Royal Commission as to be unwarrantable, and that it put a lever into the hands of the opposition, of which—as the event proved—a practised disputant like Mr Bompas did not fail to make most effective and disastrous use

Wellington College, Berks, May 25. A. IRVING

Quaternions and the "Ausdehnungslehre"

THE year 1844 is memorable in the annals of mathematics on account of the first appearance on the printed page of Hamilton's "Quaternions" and Grassmann's "Ausdehnungslehre." The "Quaternions" and Grassmann's "Ausdehnungslehre." The former appeared in the July, October, and supplementary numbers of the Philosophical Mayazine, after a previous communication to the Royal Iriah Academy, November 13, 1843 Thus communication was indeed announced to the Council of the Academy four weeks earlier, on the very day of Hamilton's ocaucany rout weeks earner, on the very day of Hamilton's discovery of quaternions, as we learn from one of his letters. The author of the "Auxidehungglehre," although not unoucous of the value of his ideas, seems to have been in no haste to place himself on record, and published nothing until he was able to give the world the most characteristic and fundamental to the contract of the contract o mental part of his system with considerable development in a treatise of more than 300 pages, which appeared in August

iffeating to more time. See the second process of the second proce Historical justice, and the interests of mathematical science, seem to require that the allisions to the "Ausdehnungslehre" in the article on "Quaternions," in the last edition of the "Encyclopædia Britannica," and in the third edition of Frof. Tait's "Treatise on Quaternions," should not be allowed to pass without protest

It is principally as systems of geometrical algebra that qua ternions and the "Ausdehnungslehre" come into comparison "To appreciate the relations of the two systems, I do not see how we can proceed better than if we ask first what they have in common, then what either system possesses which is peculiar to uself. The relative extent and importance of the three fields, itself. The relative extent and importance of the three helds, that which is common to be two systems, and those which are pecalist to each, will determine the relative rank of the geometrical algebras. Questions of priority can only relate to the field common to both, and will be much simplified by having the limits of that field clearly drawn

Geometrical addition in three dimensions is common to the

to systems, and seems to have been discovered independently both by Hamilton and Grassmann, as well as by several other persons about the same time. It is not probable that any especial chiam for priority with respect to this principle will be unged for either of the two with which we are now concerned.

The functions of two vectors which are represented in quaternions by Saß and Vaß are common to both systems as published in 1844, but the quaternion is peculiar to Hamilton's. The linear vector function is common to both systems as allimited yelevoleps, although mentioned only by Grassmann as mately developed, although mentioned only by Grassmann as

early in 1844.

To those stready acquainted with quaternions, the first quanton will naturally be: To what extent are the geometrical method which are unually called quaternione peculiar to be a superior with the properties of t early as 1844. understanding the functions Sad and Vag, but having no occuption of the quaternion ag, or at least could be made so by triffing changes of notation, as by writing S or V in place where they would not affect the value of the expressions. For such a text the examples and illustrations in treatises on quasimeter of the control of places and the control of the control of the control of places and the control of the straight of the control of inc and pane, the sphere and cyclic cone, surfaces of the second degree, geometry of curves and surfaces, hatematics, statics and kinetics of a rigid system, special kinetic problems, geometrical and physical optics, electrodynamics, general expressions for the action between linear elements, application of v to certain

physical analogies, pp 160-371, except the examples (not worked out) at the close of the chapters. worked out) at the crose of the chapters.

Such an examination will show that for the most part the
methods of representing spatial relations used by quaternoone
writers are common to the systems of Hamilton and Grassmann
To an extent comparatively limited, cases will be found in which
the quaternoone idea forms an essential element in the agnifica-

tion of the equations.

გი

into of the equations.

The question will then arise with respect to the comparatively limited field which is the peculiar property of Hamilton, How moportain zer is advantaged to be gained by the use of, the quaternion? This question, unlike the preceding, is one nato which a personal equation will necessaryly setter. Everyone which a personal equation will necessaryly setter. Everyone that it his that it may be safely affirmed that in the municipal of cases in this field the advantage derived from the use of the quaternion is elther doubtful or very infling. There remains a resideam of cases in which a substantial advantage in gained by the use of the quaternionic method. Such cases, however, the proposal of the control of the property of the control of the property of We have now to inquire what we find in the "Ausdehnungs-

lehre" in the way of a geometrical algebra, that is wanting in eare: In the way or a geometrical sigeora, that is wanting in quaterions. In addition to an algebra of vectors, the "Aps-dehnungslehre" afford's a system of geometrical algebra in which the point is the fundamental element, and which for conve-nience I shall call Grassmann's algebra of points. In this algebra we have first the addition of points, or quantities located at points, which may be explained as follows. The equation

$$aA + bB + cC + &c = cE + fF + &c,$$

in which the capitals denote points, and the small letters scalars (or ordinary algebraic quantities), significant that

$$a + b + c + &c. = e + f + &c.,$$

and also that the centre of gravity of the weights a, b, c, &c., at the points λ , B, C, δC , α , is the same as that of the weights ϵ , f, δC , at the points K, F, δC . (will be understood that negative weights are allowed as well as positive.) The quation in thus equivalent to four equations of ordinary algebra. In this Grassmann was anticipated by Mobils ("Barycentrischer Caleul,"

We have next the addition of finite straight lines, or quantities located in straight lines (Liniengrossen). The meaning of the

will perhaps be understood most readily, if we suppose that each member represents a system of forces acting on a rigid body. The equation then sugnifies that the two systems are quaralent. An equation of this form is therefore equivalent to six ordinary equations. It will be observed that the *Littimguston* AB and CD are not simply vectors, they have not merely length and direction, but they are also located each in a merely length and direction, but they are also located each in a given line, although their position within those lines is immaterial In Clifford's terminology, AB is a rotor, AB + CD a motor. In the language of Prof. Ball's "Theory of Screws," AB + CD represents either a twist or a wrench.

MAY 28, 1801

We bave next the addition of plane surfaces (Plangrossen), The equation

signifies that the plane JKL passes through the point common to the planes ABC, DEF, and GHI, and that the projection by parallel lines of the triangle JKL on any plane is equal to the sum of the projections of ABC, DEF, and GHI on the same sum of the projections of ADC, DCT, and OTAL on the same plane, the areas being taken positively or negatively according to the cyclic order of the projected points. This makes the equation equivalent to four ordinary equations

Finally, we have the addition of volumes, as in the equation

where there is nothing peculiar, except that each term repre-sents the six-fold volume of the tetrahedron, and is to be taken positively or negatively according to the relative position of the oints

points
We have also multiplications as follows:—The line (Linear,
prost) AB is regarded as the product of the points An AB.
The Flangroux ABC, which reprivatis the double area of the
the Flangroux ABC, which reprivates the double area of the
and C, or as the product of the line AB and the point C, or of
BC and A, or indeed of BA and C. The volume ABCD, which
represents six times the setrabedron, is regarded as the product of
the points A, B, C, and D, or as the product of the point A, and
the Plangroux BCD, or as the product of the lines AB and
the Regarder and the product of the lines AB and
the Regarder and the product of the lines AB and
the Regarder and the product of the lines AB and
the Regarder and the product of the lines AB and
the Regarder and the product of the lines AB and

This does not exhaust the wealth of multiplicative relation which Grassmann has found on the very elements of geometry. The following products are called regressive, as distinguished from the progressive, which have been described. The product of the Planguisten ABC and DEF interest, which is equal in numerical the planes ABC and DEF interect, which is equal in numerical value to the product of the double areas of the triangles ABC and DEF multiplied by the sine of the angle made by the planes. The product of the Linning oise AB and the Plangrosse CDE is the point of intersection of the line and the group CDE is the point of mersection of the line and the plane with a numerical coefficient representing the product of the length of the line and the double area of the triangle multi-plied by the sine of the angle made by the line and the plane. The product of three Plangroises is consequently the point common to the three planes with a certain numerical coefficient. In plane geometry we have a regressive product of two Limen-gross, which gives the point of intersection of the lines with certain numerical coefficient.

certain numerical coemicent. The fundamental operations relating to the point, line, and plane are thus translated into analysis by multiplications. The immense flexibility and power of such an analysis will be appreciated by anyone who considers what generalized multiplication in connection with additive relations has done in other fields, as in quaternions, or in the theory of matrices, or in the algebra of logic. For a single example, if we multiply the equation

$$AB + CD + &c. = EF + GH + &c.$$

The field in which Grassmann's algebra of points, as distinguished from his algebra of vectors, finds its especial application and utility, is nearly coincident with that in which, when we use the methods of ordinary algebra, tetrahedral or anharmonic or memora or rottniny sugeous, ternateurs or animal moral co-ordinates are more appropriate than rectilinear. In fact, Grassmann's aigebra of points may be regarded as the applica-tion of the methods of multiple algebra to the notions connected with tetrahedral co-ordinates, just as his or Hamilton's algebra of vectors may be regarded as the application of the methods of multiple algebra to the notions connected with rectilinear co-ordinates. These methods, however, carried the field to which they are applied with new notions. The first control of the co co-ordinates, is very much greater than when it takes the pro-of three co-ordinates, for the same reason that a multiple algebra taking the place of three co-ordinates is very much more useful taking the place of three co-ordinates is very much more useful than one taking the place of two. Grassmann's algebra of points will always command the admiration of geometers and analysts, and furnishes an instrument of marvellous power to the er, and in its general form, as applicable to space of any number of dimensions, to the latter. In the physicist an algebra of points is by no means so indispensable an instrument as an

algebra of vectors.

Grassmann's algebra of vectors, which we have described as coincident with a part of Hamilton's system, is not really anything separate from his algebra of points, but constitutes a part of it, the vector arising when one point is subtracted from another. Yet it constitutes a whole, complete in itself, and we may separate it from the larger system to facilitate comparison with the methods of Hamilton.

with the methods of Hamilton. We have, then, as geometrical algebras published in 1844, an algebra of vectors common to Hamilton and Grassmann, augmented on Hamilton's side by the quaternion, and on Grassmann's by his algebra of points. This statement should be mann's by his algebra of points. This statement should be made with the reservation that the addition both of vectors and

made with the reservation that the addition to out or vectors and of points had been given by earlier writers.

In both systems as finally developed we have the linear vector function, the theory of which is identical with that of strains and rotations. In Hamilton's system we have also the linear quaterions function, and in Crassanann's the linear function applied to the quantities of his algebra of points. This function applied to the quantities of his algebra of points. This application gives those transformations in which projective properties are preserved, the doctrine of reciprocal figures or many properties are preserved, the doctrine of reciprocal figures or many properties are properties and properties are the account of the properties and the theory of marrices, but we are here considering only the geometrical side of the theory.)

In this earliest writings on quaternions, Hamilton does not discuss the linear function.

(1853), he treats of the inversion of the linear vector function. (1833), he treats of the inversion of the linear vector function, as also of the linear quaternois function, and shows how to find as also of the linear quaternois function, and shows how to find the state of the case of t to the quaternion function.

In Grassmann, although the linear function is mentioned in the first "Ausdehoungslehre," we do not find so full a dis-cussion of the subject until the second "Ausdehoungslehre" (1862), where he discusses the latent roots and axes, or what corresponds to axes in the general theory, the whole discussion relating to matrices of any order. The more difficult cases are included, as that of a strain in which all the roots are real, but there is only one axis or unchanged direction. On the formal side he shows how a linear function may be represented by a quotient or sum of quotients, and by a sum of products, uckenausdruck.

Luckensustanck.
More important, perhaps, than the question when this or that theorem was find published in the question where we first find theorem was find published in the question where we first find of linear functions, or the algebra of instances, as as it is now generally called fin vol., xxx. p. 35, of this journal, Frod. Martines "as consustings" a second battle of Algebra is exacted as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of the first perhaps are not as the second transfer of t as a sum of a kind of products (luckenhaltse, or open), is

described in a note at the end of the first " Austlehnungslehre " There we have the matrix given not only as a sum, but as a sum of products, introducing a multiplicative relation entirely different from the ordinary mulisplication of matrices, and hardly less from the ordinary multiplication of matrices, and hardly less fruitful, but not lying nearly so near the surface as the relations to which Prof. Sylvester refers The key to the theory of matrices is certainly given in the first "Ausdehuungslehre," and if we call the birth of matricular analysis the second birth of algebra, we can give no later date to this event than the memorable year of 1844

memorable year of 1844
The immediate occasion of this communication is the following passage in the preface to the third edition of Prof Tail's
"Mammitton not only published his theory complete, the
year before the first (and extremely imperfect) sketch of the
'Austehnungsiehre' appeared, but had given ten years
before, in his provinced study of Sets, the very processes of external and internal multiplication (corresponding to the Vector external and internal multiplication (corresponding to the Vector and Scalar parts of a product of two vectors) which have been put forward as specially the property of Grassmann 'For additional information we are referred to art 'Quaternions,' 'Encyc. Brit.,' where we read respecting the first 'Audehnugliche' ...

"he particular two species of multiplication ('inner' and 'outer') of directed lines in one plane were given. The results outer) of directed lines in one plane were given. The results of these two kinds of multiplication correspond respectively to the numerical and the directed parts of Hamilton's quaternion product. But Grassmann distinctly states in his preface that he also had better to extend his method to angles in space.

had not had lessure to extend nip methou to angues in space.

But his claims, however great they may be, can in no way conflict with those of Hamilton, whose mode of nultiplying couples (in which the 'inner' and 'outer' multiplication are es-entially involved) was produced in 1833, and whose quaternion system was completed and published before Grassmann had es-entailly unrowed) was produced in 1833, and whose quaternous operation was completed and published before Grassmann had elaborated for press even the radimentary portions of his own the production to angle in space, his doct even been stacked." I shall leave the reader to judge of the accuracy of the general terms used in these passages in comparing the first "Audelmungslebre" with Hamilton's system as published in 1843 or 1844. The specific statements respectively. Thinking and Grassmann

The specime statements respecting reasonation and crassmanin require an answer.

It must be Hamilton's "Theory of Conjugate Functions or Algebraic Couples" (read to the Royal Irish Academy 1833 and 1835, and published in vol xvii. of the Transactions), to which reference is made in the statements concerning his "protracted study of Sets" and "mode of multiplying couples". But I cannot find anything like Grassmann's external or internal multiplication in this memoir, which is concerned, as the title pretty clearly indicates, with the theory of the complex quantities of ordinary algebra.

It is difficult to understand the statements respecting the "Ausdehnungslehre," which seem to imply that Grassmann's

two kinds of multiplication were subject to some kind of limitatwo kinds of multiplication were subject to some kind of imita-tion to a plane. The external product is no limited in the first "Ausdehnungslehre" even to three dimensions. The internal, which is a comparatively simple matter, is mentioned in the first "Ausdehnungslehre" only in the preface, where it is defined, and placed beside the external product as relating to directed There is not the least suggestion of any difference in the

products in respect to the generality of their application to vectors.

The misunderstanding seems to have arisen from the following sentence in Grassmann's preface. "And in general, in the consentence in Grassmann's preface "And in general, in the con-sidration of angles in space, difficulties present themselves, for the complete (adistrity) solution, of which I have not yet had sufficient leasure." It is not supprising that Grassmann should have required more time for the development of some parts of this system, when we consider that Hamilton, on his discovery of quaternions, estimated the time which he should wish to devote quatermons, estimated the time which he should with to devote to them at ten or fifteen years (see ha letter to Prof I att in to them at ten or fifteen years (see ha letter to Prof I att in took several years to prepare for the press as many pages as took several years to prepare for the press as many pages as when the profit of the press as many pages as when the profit of the press as the pressure of the press as the pressure of the press as the pressure of t years 1843-44. Such a comparison should be baset on the

Such a comparison I have endeavoured to make, or rather to indicate the bears on which it may be made, so far as systems of indicate the bears of the such as the such as the such as in general, I suppose that there is no question that Grassmann's system is of Indefinitely greater extension, having no limitation to any particular number of dimensions.

I. WILLARD GIBBS.

The Flying to Pieces of a Whirling Ring.

IN NATURE of May 14 (p. 31) I notice a letter by Mr. C. A. Carus-Wilson on the rotation of a hollow steel flask, composed Carus-Wilson on the rotation of a hollow steel Bask, composed apparently of a sphencialshell mounted on an axis constituting a diameter. Mr Carus-Wilson speaks of this body as being under a "tension" of "3" 3" 50 hos per square noth" at a certain speed of rotation. He does not, however, specify what is the tension to which he refers, nor where it is found, earther does he give the density and elastic constants of the material hor indicate the method by which he arrived at his result.

indicate the method by which he arrived at his result. So far as I know, the only problem of the kind which has yet been solved is that of an isotropic spherical shell 1 rotating about an imaginary axis through its centre at speeds at which the strains follow Hooke's law 1 his differs from the case Mr Carra Wilson speaks of, inasmuch as the existence of a real material axis must introduce conditions somewhat different from those assumed by the mathematical theory, and further the results obtained by this theory cannot legitimately be applied to speeds exceeding that where bulging becomes sensible, if indeed so far.

This solution is probably, however, the nearest to the According to it the strains and stresses vary throughout the

According to it the strains and stresses vary throughout the shell with the distance from the centre, and the angular distance from the exist of rotation. They also depend on the density and on the elastic properties of the material. There are also at every point three principal stresses, whereoft one it is true vanishes over the surfaces. Thus such a statement as Mr.

Carus-Wilson's requires further explanation Carus Wilson's requires further explanation
According to the two thores most commonly entertained, the

Denoting the angular velocity by ω , the radii of the outer and inner surfaces respectively by a and a', the density by ρ , Young's inner surfaces respectively by a and a, the density op ρ_1 , roung a modulus by E, the greatest strain by s, the maximum stress-difference by S, and the stress at right angles to the mendian plane by Φ , the three last quantities beling measured in the equator, the following are some of the results I found for materials in which Poisson's ratio is 1/4 -

			S/wford		20مرابيات	
	Inner	Outer	Inner	Outer	Inner	Outer
	_	-				
d/a = 0'9	0 950	0 833	1 064	n 866	0 912	o 866
negligible	10	10	10	10	10	10

Apparently in the case mentioned by Mr. Caras-Wilson, a/Jan 15/16 = 0 3275. Supposing the material to have Polsono's ratio = 1/4, which seems to accord fairly with experiments on a constraint of the properties of the strains and stresses over the surfaces for a series of values

' Cambridge Philosophical Society's Transactions, vol. xiv pp. 467-483 NO. 1126, VOL. 44]

of a'/a for materials in which Potsson's ratio is 1/4. These give by interpolation fairly accurate values for all values of a'/a. For other values of Poisson's ratio, recourse must be had to the For other values of Poisson's ratto, recourse must be had to the general formule given in the paper, unless $\epsilon_i \equiv 1 - a/a_i$, is very small, when the greatest values of z and S are given approximately by $E_z/a^2\rho g^2 = 1 - \frac{1}{2}e(1-\eta)$, $S/a^2\rho g^2 = 1 + e/(1+\eta)$, where η is Poisson's ratio (see Camh. Trans., vol. xiv. p. 304).

A Comet observed from Sunrise to Noon.

A structure ago the loan of an old number of Harper; Abenduly 1 mag ago the loan of an old number of Harper; Abenduly 1 mag ago the loan of an old number of Harper; Abenduly 1 mag and 1 mag and 1 mag and 1 mag anticle, on the origin of celestial species, by J. Norman Lockyer, F.R.S., Cor. Inst France, that set me thinking of what I behaved of the great comet of 1882, when I made its tremenobserved of the great comet of 1893, when it made its tremen-dous plunge round the sun, on September 18. At that of the sun of the Islands, and on the day mentioned—in latitude 16° 25° S. longitude 151° 57° W of Greenwich, a position about midway between the two islands Bolahola and Maupiti (the Maurias of Cook)—I saw, with the naked eye, the comet travel about 90° of Cook—I saw, with the nazed eye, the comet travel about 90 or the circle of the un's disk, between sunner and noon, but what made it most remarkable to us was that it should be possible for us, in a perfectly clear sky, to be able to watch it all, from sunrise to noon, with very hitle more distress to the eye than if in a clear night looking at a full moon

in a clear high! looking at a tuil moon. Now, Sir, may it not be that this is partly a proof of the theory set furth by Norman Lockyer in the article above mentioned, viz that comets are swarms of meteorites in collision, travelling through space, and that the outer invisible part of the swarm that formed this comer's nucleus had partially eclipsed the sun, like a veil over it? I am not aware if it was noticed by any competent astronomer or not, but the chances are that none had the splendid opportunity that we had to see the none had the splendid opportunity that we had to see the phenomena, so, Sir, knowing that men of science are always glind to get facts from observers in all parts of the world is my glind to get facts from observers in all parts of the world is my address. Thinking this, although latic, may probably be of some interest to the scientific world, I leave you to do what you may think proper with it. think proper with it Rainten, January 30

Graphic Daily Record of the Magnetic Declination or Variation of the Compass at Washington

THE REJUVENESCENCE OF CRYSTALS.

TERY soon after the invention of the microscope, the value of that instrument in investigating the pheno-

value of that instrument in investigating the pheno-mena of crystallization began to be recognized. The study of crystal-morphology and crystallogenesis was initiated in this country by the observations of Robert Boyle; and since his day a host of investigators-among whom may be especially mentioned Leeuwenhoek and Vogelsang in Holland, Link and Frankenheim in Ger-many, and Pasteur and Senarmont in France—have added many, and Pasteur and senamont in rance—nave anden largely to our knowledge of the origin and development of crystalline structures. Nor can it be said with justice that this field of investigation, opened up by Enghish pioneers, has been ignobly abandoned to others, for the credit of British science, has been fully maintained by the numerous and brilliant discoveries in this department of knowledge by Brewster and Sorby,

There is no branch of science which is more dependent for its progress on a knowledge of the phenomena of for its progress on a knowledge of the phenomena of crystallization than geology. In seeking to explain the complicated phenomena exhibited by the crystalline masses composing the earth's crust, the geologist is

The Friday Evening Discourse, delivered at the Royal Institution on touary 30, 1891, by Prof John W Judd, F R S.

NO. 1126, VOL. 44]

constantly compelled to appeal to the physicist and chemist; from them alone can he hope to obtain the light of experiment and the leading of analogy, whereby he may hope to solve the problems which confront him.

But if geology owes much to the researches of those physicists and chemists who have devoted their studies to the phenomena of crystallization, the debt has been more than repaid through the new light which has been thrown on these questions by the investigation of naturally-formed

crystals by mineralogists and geologists
In no class of physical operations is time such an inportant factor as in crystallization; and Nature, in producing her immittable examples of crystalline bodies, bas been unsparing in her expenditure of time. Hence it is not surprising to find that some of the most wonderful phenomena of crystallization can best be studied—some, indeed, can only be studied—in those exquisite specimens of Nature's handswork which have been slowly claborated by her during periods which must be measured in millions of vears.

I propose to-night to direct your attention to a very curious case in which a strikingly complicated group of phenomena is presented in a crystalline mass; and these phenomena, which have been revealed to the student of natural crystals, are of such a kind that we can scarcely hope to reproduce them in our test-tubes and crucibles

But if we cannot expect to imitate all the effects which have in this case been slowly wrought out in Nature's laboratory, we can, at least, investigate and analyze them; and, in this way, it may be possible to show that phenoand, in this way, it may be possible to show that pheno-mena like those in question must result from the pos-session by crystals of certain definite properties. Each of these properties, we shall see, may be severally illus-trated and experimentally investigated, not only in natural products, but in the artificially-formed crystals of our laboratories.

In order to lead up to the explanation of the curious phenomena exhibited by the rock-mass in question, the first property of crystals to which I have to refer may be enunciated as follows - -

Crystals possess the power of resuming their growth after interruption, and there appears to be no limit to the time after which this resumption of growth may take

It is a familiar observation that if a crystal be taken from a solution and put aside, it will, if restored after a longer or shorter interval to the same or a similar solution, continue to increase as before But geology affords innumerable instances in which this renewal of growth in crystals has taken place after millions of years must have elapsed Still more curious is the fact, of which abundant proof can be given, that a crystal formed by one method may, after a prolonged interval, continue its growth under totally different conditions and by a very different method. I hus, crystals of quartz, which have clearly been formed in a molten magma, and certain inclosures of glass, may continue their growth when brought in contact with solutions of silica at ordinary temperatures. In the same way, crystals of felspar, which have been formed in a mass of incandescent lava, may increase in size, when solvent agents bring to them the necessary materials from an enveloping mass of glass, even after the whole

It is this power of resuming growth after interruption, which leads to the formation of zoned crystals, like the fine specimen of amethyst enclosed in colourless quartz. which was presented to the Royal Institution seventy years ago by Mr Snodgrass.

The growth of crystals, like that of plants and animals,

is determined by their environment; the chief conditions affecting their development being temperature, rate of growth, the supply of materials (which may vary in quality as well as in quantity), and the presence of cortain foreign bodies.

It is a very curious croumstance that the form assumed by a crystal may be completely altered by the presence of minutesimal traces of certain foreign substances, be it remarked, which do not enter in any way into the composition of the crystallizing mass. Thus there are certain crystals which can only be formed in the presence of water, fluorides, or other sails. Such foreign bodies, which exercise an influence on a crystallizing substance without entering into its composition, have because without entering into its composition, have because of the bodies known to chemists as "ferments," so many of which are now proved to be of organic origin of which are now proved to be of organic origin of which are now proved to be of organic origin.

Studied according to their mode of formation, zoned crystals fall naturally into several different classes

In the first place, we have the cases in which the successive shells or zones differ only in colour or some other accidental character. Sometimes such differently coloured shells of the crystal are sharply cut off from one another, while in other instances they graduate imperceptibly one into the other.

can be seen that the control of the

Some very interesting varieties of minerals, like the Cotterite of Ireland, the red quartz of Cumberland, and the spotted amethyst of Lake Superior, can be shown to owe their peculiarities to thin bands of foreign matter sonally included in them during their growth

A currous class of soned crystals arises when there is a change in the habit of a crystal during its growth. Thus, as Lavalle showed in 1851 (Bull Gol Soc Parts, 2me set, vol viu. pp. 610-13), if an octahedron of alum be substance, and then a quantity of alkaline carbonste be added to the liquid, the octahedral crystal, without change in the length of its axes, will be gradually transfermed into a cube In the same way, a scalenohedron of calcite may be found inclosed in a prismatic crystal of the same in both crystals in of the vertical axis being the same in both crystals in the crystals in the crystals in the crystals in the crystal crystal crystals in the crystal crystal crystal crystals in the crystals in the crystal crystal crystal crystal crystals in the crystal crystal

By far the most numerous and important class of soned crystals is that which includes the forms where the successive sones are of different, though analogous, chemical composition. In the case of the alums and garnets, we may have various stomorphous compounds forming the successive zones in the same crystall; while, in substances crystallizing in other systems than the cubic, we flat compounds forming the different enclosing shells.

audits, and the cases are illustrated by many artificial crystals, and by the tourmalines, the epidotes, and the felspass among minerals. The zones, consisting of different materials, are sometimes separated by well-marked planes; but in other cases they shade imperceptibly into one another

In connection with this subject it may be well to point out that zoned crystals may be formed of two substances

which do not crystallize in the same system. Thus, crystals of the monoclinic augite may be found surrounded by a zone of the rhombic enstatute; and crystals of a trichnic felspar may be found enlarged by a monoclinic

heispan. Still more curious is the fact that, where there is a similarity in crystalline form and an approximation in the dominant angles (plesomorphism), we may have soming and intergrowth in the crystals of substances. Senarmont showed in 18f6, a cleavage-thomb of the natural calicic carbonate (calcite), when placed in a solution of the sodic intrate, becomes enveloped in a sone of this latter substance, and Tichermak has proved the agreeous one if tested by its cleavage, by its susceptibility to twin lamellation, or by the figures produced by ething In the same way, arrons, which are composed of the two oxides of silicon and airconium, are found grown in composite crystals with xenotime, a phosphate

of the metals of the cerium and strium groups. These facts, and many similar ones which might be addited, point to the conclusion that the beautiful theory of isomorphism, as originally propounded by Mitscherick, stands in need of much revision as to many important details, if not, indeed, of complete reconstruction, in the light of modern observation and experiment

The second property of crystals to which I must direct your attention is the following -

If a crystal be broken, or mutilated in any way whatever, it possesses the power of repairing its injuries during subsequent growth.

As long ago as 186, Frankenhem showed that, if a drop of a started solution be allowed to evaporate on the stage of a microscope, the following interesting observations may be made upon the growing crystals. When they are broken up by a rod, each fragment tends to re-form as a perfect crystal, and if the crystals be caused to be partially re-dissolved by the addition of a minute drop of the mother liquor, further evaporation causes them to resume their original development (Pogg. Alm., Bd xxxv., 1856)

In 1842, Hermann Jordan showed that crystals taken from a solution and mutilated gradually became repared or healed when replaced in the solution (Multer Archiv. fur 1842, pp. 46-56) Jordan's observations, which were published in a medical journal, do not, however, seem to have attracted much attention from the physicists and chemists of the day.

Lavalle, between the years 1850 and 1853, and Kopp, in the year 1855, made a number of valuable observations bearing on this interesting property of crystals (Letony Am, curv., 1855, pp. 118-25). In 1856 the subject was more thoughly suddle by times investigators who puber of the property of the subject was marked to the property of the property of

As long ago as 1851, Lavalle had asserted that, when one solid angle of an octahedron of alum is removed, the crystal tends to reproduce the same mutilation on the opposite angle, when its growth is resumed! This remarkable and anomalous result has, however, by some subsequent writers been explained in another way to that suggested by the author of the experiment.

In the same way the curious experiments performed at a subsequent date by Karl von Hauer, experiments which led him to conclude that hemihedrism and other pecu-

* Bull Geel Set Parts, ame ser, vol van pp 610-13, 1851, Mosgao, (eamet, 11, 1853, pp 454-56, (empt rend , xxxvi , 1853, pp, 403-05

liarities in crystal growth might be induced by mutilation.1 have been asserted by other physicists and chemists not to justify the starting conclusions drawn from them at the time. It must be admitted that new experiments bearing on this interesting question are, at the present time greatly needed.

In 1881, Loir demonstrated two very important facts with regard to growing crystals of alum (Compt rend, Bd. xcii. p 1166) First, that if the injuries in such a crystal be not too deep, it does not resume growth over its general surface until those injuries have been repaired Secondly, that the injured surfaces of crystals grow more rapidly than natural faces. This was proved by placing artificially-cut octahedra and natural crystals of the same

size in a solution, and comparing their weight after a certain time had elansed.

The important results of this capacity of crystals for undergoing healing and enlargement, and their application to the explanation of interesting geological phenotion to the explanation of interesting geological phenomena has been pointed out by many authors. Sorby has shown that, in the so-called crystalline sand-grains, we have broken and worn crystals of quarte, which, after many vicissitudes and the lapse of millions of years, have grown again and been enveloped in a newly formed quartz-crystal. Bonney has shown how the same phenomena are exhibited in the case of mica, Berke and Whitman Cross in the case of hornblende, and Merrill in the case of augite In the felspars of certain rocks it has been proved that crystals that have been rounded, cracked, corroded, and internally altered-which have, in short, suffered both mechanical and chemical injuries -be repaired and enlarged with material that differs considerably in chemical composition from the original crystal

It is impossible to avoid a comparison between these phenomena of the inorganic world and those so familiar to the biologist lt is only in the lowest forms of animal life that we find an unlimited power of repairing injuries in the Rhizopods and some other groups a small fragment may grow into a perfect organism. In plants the same phenomenon is exhibited much more commonly, and in orms belonging to groups high up in the vegetable series. Thus, parts of a plant, such as buds, bulbs, slips, and grafts, may -sometimes after a long interval-be made to grow up into new and perfect individuals. But in the mineral kingdom we find the same principle carried to a much farther extent. We know, in fact, no limit to the minuteness of fragments which may, under favourable conditions, grow into perfect crystals—no bounds as to the time during which the crystalline growth may be suspended in the case of any particular individual.

The next property of crystals which I must illustrate, in order to explain the particular case to which I am calling

order to expan the particular case to which I am sample your attention to night, is the following: Two crystals of totally different substances may be developed within the space bounded by certain planes, becoming almost insertricably intergrown, though each retains its distinct individuality.

This property is a consequence of the fact that the substance of a crystal is not necessarily continuous within the space inclosed by its bounding planes Crystals often exhibit cavities filled with air and other foreign substances In the calcite crystals found in the Fontainebleau sandstone, less than 40 per cent. of their mass consists of calcic carbonate, while more than 60 per cent is made up of grains of quartz-sand, caught up during crystalliza-

In the rock called "graphic granite," we have the minerals orthoclase and quartz intergrown in such a way that the more or less isolated parts of each can be shown, by their optical characters, to be parts of great mutually interpenetrant crystals Similar relations are shown in the so-called micro-graphic or micro-pegmatitic intergrowths of the same minerals which are so beautifully exhibited in the rock under our consideration this evening

There is still another property of crystals that must be kept in mind, if we would explain the phenomena

exhibited by this interesting rock

A crystal may undergo the most profound internal changes, and these may lead to great modifications of the optical and other physical properties of the mineral, yet, so long as a small-often a very small-proportion of its molecules remain intact, the crystal may retain, not only its outward form, but its capacity for growing and

repairing injuries
Crystals, like ourselves, grow old Not only do they suffer from external injuries, mechanical fractures, and chemical corrosion, but from actions which affect the whole of their internal structure Under the influence of the great pressures in the earth's crust, the minerals of deep-scated rocks are completely perineated by fluids which chemically react upon them. In this way, negative crystals are formed in their substance (similar to the beautiful "ice-flowers" which are formed when a block of ice is traversed by a beam from the sun or an electric lamp), and these become filled with secondary products As the result of this action, minerals, once perfectly clear and translucent, have acquired cloudy, opalescent, indescent, avanturine, and "schiller" characters, and minerals, thus modified, abound in the rocks that have at any period of their history been deep-seated. As the destruction of their internal structure goes on, the crystals gradually lose more and more of their distinctive optical and their physical properties, retaining, however, their external form, till at last, when the last of the original molecules is transformed or replaced by others, they pass into those mineral corpses known to us as "pseudo morphs."

But while crystals resemble ourselves in "growing old," and, at last, undergoing dissolution, they exhibit the remarkable power of growing young again, which we, alas i never do fhis is in consequence of the following remarkable attribute of crystalline structures

It does not matter how far internal change and dis-integration may have gone on in a crystal—if only a certain small proportion of the unaltered molecules re-main, the crystal may renew its youth and resume its growth

When old and much-altered crystals begin to grow again, the newly-formed material exhibits none of thus marks of "senity" to which I have referred The sand-grains that have been battered and worn into microscopic pebbles, and have been rendered cloudy by the develop-ment of millions of secondary fluid cavities, may have clear and fresh quartz deposited upon them to form crystals with exquisitely perfect faces and angles The white, clouded, and altered felspar-crystals may be enveloped by a zone of clear and transparent material, which has been added millions of years after the first formation and the subsequent alteration of the original crystal

We are now in a position to explain the particular case which I have thought of sufficient interest to claim your attention to-night.

In the Island of Mull, in the Inner Hebrides, there exist masses of granite of Tertiary age, which are of very great interest to the geologist and mineralogist. In many places this granite exhibits beautiful illustrations of the curious intergrowths of quartz and felspar, of which I have

NO. 1126, VOL. 44]

already spoken. Such parts of the rock often abound with cavities (druses), which I believe are not or original but of secondary origin. At all events, it can be shown that these cavities have been localities in which crystal growth has gone on—they constitute indeed veritable laboratories of withetic nursealogy.

Now, in such cavities the interpenetrant crystals of quarts and felapar in this rock have found a space where they may grow and complete their outward form; and its curous to see how sometimes the quarts has prevailed over the felapar and a pure quart-crystal has been resulted, and up the at other times the opposite effect has resulted, and up the part and the control of the part and the

Those relations can be fully made out when thin sections of the rock are examined under the microscope by the aid of polarized light, and they speak eloquently of the possession by the crystals of all those curious peculiarities of which I have reminded you this evening

By problems such as those which we have endeavoured to solve to-night, the geologist is beset at every step. The crust of our globe is built up of crystals and crystal fragments—of crystals in every stage of development, of growth, and of variation—of crystals undergoing change, decay, and dissolution. Hence the study of the natural history of crystals must always constitute one of the main foundations of geological senior, and the future progress constitution of the control of the

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

A VIGOROUS attempt is being made by ignorant and prejudiced persons to prevent the establishment of a National Hygenic Institute worthy of the United Kingdom. A deputation will wait upon Sir Michael Hicks-Beach, President of the Board of Trade, on Friday, june 5, to submit to him an exact statement of the facts relating to the matter. Meanwhile, the Executive Committee has susued the following circular.—

On Monday afternoon, July 1, 1880, a meeting was held at the Mansion House, under the Presidency of Strategy of the Monday of the Presidency of Strategy of the Monday of the Land of the Presidency of Strategy of London, 'for the purpose of hearing statements from Str James Paget, and other representatives of scientific and medical opinion, with regard to the recent increase of rables in this country, and the efficacy of the treatment discovered by M Pasteur for the prevention of hydrophobics.

Although convinced of the advantages likely to accrue to the community at large by the founding of a Bactier of the community at large by the founding of a Bactier of the community at large by the founding of a Bactier of the large state of

Acting on the advice of their solicitors, Messrs. Hunters and Haynes, the Executive Committee decided to incorporate the Institute as a limited liability company, with the omission of the word "Limited," in order to impress

the public with the fact that the Institute was not established for purposes of gain, but for purely charitable and scientific objects.

The application was lodged at the Board of Trade on February 13, 1891, and, shortly afterwards, a number of petitions were sent in asking the Board of Trade to withhold its license, as the objects of the Institute "clearly pointed to experiments on living animals." As Chairman of the Committee, Sir Joseph Lister then wrote to the President of the Board of Trade, showing why, in the opinion of the Committee, their opponents should not gain their point. In the first place, he pointed out that the granting of a vivisection license is not within the province of the Board of Trade, but under the control of the Secretary of State for the Home Department In the second place, he clearly proved that it is absolutely necessary that the Institute should be licensed in the manner described, for it could not be registered under the Companies Act, 1862, without most seriously inter-fering with its prospects. From counsel's opinion it is evident that, should the Institute be registered as an ordinary limited hability company under the Act, it would at any time be possible for the members to wind up the company and divide the funds of the Institute; whereas the Board of Trade, in granting the license asked for, would make it a condition that all the property of the Institute should be applied to the advancement of science and kindred subjects only, and not be distributed among the members. In this way only could security be given that the funds would be applied for the purposes intended

This letter was posted by one of the secretaries on May 12, 1861; but on the same day the solicitors to the Executive Committee received a letter from the President of the Board of Trade, who, without giving any reason whatever for his decision, declined to grant the application. On the next day, however, Sir Joseph Lister received a letter in answer to that posted on May 12, in which the President of the Board of Trade numsted his

willingness to receive a deputation on June 5 at 11 a.m. Workers in bacternological scenee are now labouring under considerable difficulties, as there is no place in the United Kingdom specially fitted for such research. By the establishing of this Institute, they would be placed in the best possible conditions for carrying out original investigations. Moreover, a central Institute for the systematic teaching of bacteriology would be provided, not only for medical men, but also for veterinary surgeons, chemists, agriculturists, &c.

At present, in apte of the efforts made in this direction by several methical schools, most of the English workers who with to gain special knowledge in bacterology, are compelled to go to the Continental laboratories for their instruction. The question, therefore, which the Board Trade will have to decide it, whether such a state of things should continue, or whether England should have to will be continued to the state of things should continue, or whether England should have to will be continued to the sound the state of the stat

NOTES.

We are informed that Kew has recently acquired by purchase from Mr. F. Cuttis, a descendant of William Cutts, the founder of the Botanical Magazini, about 1650 original drawings, theirly of figures which appeared in this publication. They belong partly to the first series and partly to the second, from 1800 to 1826—that is only, during the period that the magazine was edited by Dr. Sina. Many of these drawings are very beautiful, and very carefully coloured, appealuly those done by James

Sowerby and Sydenham Edwards; but some of the finest of their work was not reproduced in the plates. The collection also includes some of the poorest work that ever appeared in the magazine. In 1815 Sydenham Edwards seceded, and worked for the rival Botanical Register; Sowerby had ceased contributing, and there seems to have been a lack of novelties for illustration. Towards the end of Dr Sims's editorship, in 1826, the Botanical Magazine was doubtless supplanted in a great measure by the Balanical Register then conducted by the vigorous Lindley. Its circulation greatly decreased, and the impression was small : hence this series is very rare. The following year, however, Sir William Hooker became editor and speedily raised both the artistic and botanical character of the magazine Many of the plates published during the latter half of Dr Sims's editorship are not signed, but all the drawings are, and we learn that William Hooker, the artist of the Paradicus Londonensis. was an occasional contributor. The collection also contains a number of unpublished drawings.

THE Council of the Institution of Naval Architects has resolved to award the gold medal of the Institution to Prof V. B. Lewes for his paper on boiler deposits, read at the Institution's recent annual general meeting.

The President of the Royal Society, who is Chairman of the Board of Visitors, will hold the annual visitation of the Royal Observatory at Greenwich on Saturday, June 6 next. The Observatory will be open for inspection at 3 pm.

MR. JAMES E KEELER, the Astronomer of the Lick Observatory, has lately been appointed Director of the Alleghany Observatory, in succession to Mr S. P Langley, Secretary of the Smithsonian Institution

A CZECH Academy of Sciences was opened at Prague on the 18th inst, by the Archduke Charles Louis The Lain title of the Academy is Bohemica Scientiarum, literarum et artum Academa Imperatoris Frantisci Josephi, the President is Josef Hildrick, and the General Secretary Dr. F J Studmicks.

An extra evening meeting of the Royal Institution will be held on Tuesday, June 2, at nine o'clock, when Dr. Charles Waldstein will give a discourse on the discovery of "The Tomb of Aristotle."

ANMIANN papers announce the death of Prof. J. F. Illigard, late superintendent of the U.S. Coast Surrey. It is want on at Zwebrucken in 1828, went to America with his dahron at Zwebrucken in 1828, went to America with his dahron 1838, and enterted the serves of the U.S. Coast Surrey in 1829. "His work," says the New York. Nation, "thy directly in the cof his profession, in the improvement of methods, the determination of weights and unsasures, and the novel method of accertainty the differences of longitude by telegraph. His publications on those subjects are to be found chiefly in the Coast Surrey Reports. One of the most noteworkly relates to

NO. 1126, VOL. 447

the telegraphic determination of the differences of longitude between Greenwich, Pars, and Washington. He was delegue to the International Meric Commission in 1872, and a member of the International Bureau of Weights and Messares, of which he decilined the directorabilip. He was an original member of the National Audemy of Sciences, and for some years list Home Secretary. In 1874 be was elected President of the American Association for the Advancement of Science. His neceeded to the work of Baches in connection with the work of the Bareau of Weights and Messares, and took a leading part in preparing exact metric standards for distribution to the States and Territoriese.

THE recent botamical mission of Mr. D. Morris to the West Indies forms the subject of the Kew Bulletin for May and June, The Bullutin publishes the official correspondence recording the circumstances under which the Imperial Government assented to Mr. Morru's mission, and reproduces his report to the Secretary of State for the Colonies

THE Kee Bulletin does good servee by publishing lists of parten glasts annually decribed in bostness and abortenitural publications, both boglish and foreign. In Appendix II., 1807, there is a list which compares all the new introductions recorded during 1800. "These lists," says the Bulletin, "are independent between the commentation of correct connectiative, especially in the smaller botanical establishments in correspondence with Kew, which are, as a rule, only scannily provided with bortecultural periodicals. Such a list will also afford information respecting one plants under estilustation at this establishment, many of which will be distributed from it in the regular course of exchange with other botanic garders."

On the 13th inst. the Council of the county borough of Boole deceded to appropriate and set aude for the purpose of technical education the whole of the portion of the Exchaquer contribution account which mays to be used under the provision of the Local Taxatlon (Dustoms and Excue) Act, 1850 The Free Lihray and Museum Committee were centrated with the carrying out of a scheme submitted by them to the Council, Contribution of the Council Counc

life following is an extract from the Times of last week which may interest many of our readers -Some months ago a company, which had been formed at Wheeling, West Virginia, for the purpose of "developing" that city, began to drill a well in search of petroleum or natural gas. A depth of over 4100 feet was reached, and in this distance a dozen thick veins of coal are said to have been passed, while petroleum and gas have both been struck-though not in paying quantities-and gold quartz, iron ore, and many other minerals have been brought to the surface. The officers of the Geological Survey at Washington, according to a Wheeling despatch, have become very interested in the proceeding, and "the hole will be drilled to a depth of one mile " After this the Government will take up the work under the direction of two expert officers of the Survey, and the drilling will be continued into the earth as far as human skill can penetrate. The object is to ascertain the thermometric and magnetic conditions as far as possible

This Transandine Railway across the Andes, connecting the Argentine railway system with that of Chil, has been the subject of an interesting article in Engineering. Our contemporary in its issue of this week again deals with this fine piece of engineering, and describes the tunnelling plant used, as well as the dutribution by electrical means of the power available and uncessary for driving the air compressors for the Ferroux rock

drills used. This line across the Andes consists of a series of tunnels and other heavy works; the tunnels had to be bored in most inaccessible regions, where the means of transport are measure in the extreme. The whole of the plant therefore had to be designed with great care and with special reference to the unusual requirements. Weight had to be minimized, and strength and simplicity had to be carefully obtained. Waterpower was available at some distance from the scene of operations : the water-power was brought to the primary stations by means of 20-inch steel pipes. On the Chilian side the primary station contained ten dynamos and two spare ones, each being of 80 horse-power, and each coupled direct to, and driven by, a Girard turbine. The electric power generated is transmitted through a cable to secondary stations, where, by means of motors, the air-compressors are operated A similar arrangement is in use on the Argentine side, only the dynamos are of 40 horse-power, because they had to be transported over mountains on mules' backs, which made it necessary to minimize the weight. This use of the electrical transmission of power in highly interesting, the circumstances being such that, without it, the boring of the tunnels would have been a work of great expense and magnitude.

Globar has received information from Japan to the effect that there is an increasing reaction in the country against forelign influences. This is said to be especially visible in schools where European instruction is given. The such schools, one of which formerly had 300 pupils, the other 150, have been obliged to combine their forces, having no more than 150 pupils between them. At the University of Tokio the number of native lecturers increases, while that of the foremer wall discresses.

In the New York Sun, Mr G F Kunz, the well-known expert in gems, has recently called attention to a property of the diamond which may serve as a means of distinguishing it from other substances. Referring to the paper of Robert Boyle "On a Remarkable Diamond that Shines in the Dark," oublished in the Transactions of the Royal Society in 1663, Mr. Kunz remarks that this paper has been indirectly alluded to by a number of authors, but never read. Among a quantity of facts Boyle mentions one diamond that phosphoresced simply by the heat of the hand, absorbed light by being held near a candle, and emitted light on being rubbed. He stated that many diamonds emitted light by being rubbed in the dark. The experiments made by Mr. Kunz show conclusively not only that Boyle's statement that some dismonds phosphoresce in the dark after exposure to the sunlight or an arc of electric light is true, but also that all diamonds emit light by rubbing them on wood, cloth, or metal, a property which will probably prove of great value in distinguishing between the diamond and other hard stones, as well as paste, none of which exhibit this phenomenon, and will be welcomed by the general public who do not possess the experience of the dealer in diamonds. The property is evidently not electric, or it would not be visible on being rubbed on me al

We learn from the American Misterological Journal for Applith the appropriation for the new Weather Service of the United States in 579,753 dollars, being an increase of 629,790 dollars on the amount for the current year. This is accounted for by the addition of 50,000 dollars for the proposed extension of the service in agricultural regions, and by the fact that, inder the present arrangement, five of the leading officials were sugged from the army, and their states must theseforward sugged to the army, and their states must theseforward area. The Child of the Service is to receive 4500 dollars a year. No appointment has yet been made to this position. It is quite possible that the present Chief Signal, Officer will be cleasized from the army for this day, and Prof Abbe, Prof. W.

M Davis, Prof. Nipher, and Dr. Hunrich are some of the other propilents meterorlogists mentioned as possible candidates. The same fournal also reports that Dr. Baker, Secretary of the Michaga State Board of Health, has investigated the cause of influena. He stated that the germs are at all times present, but that there must be certain connodent meteorological conditions to irritate the threat and air passages afficiently to let the germ gain an entrance to the body. These softiments of the property of the state of the property of north and north-east words, and the excessive amount of orose demng the past three months.

MR. C. L. WRAGGE has issued a circular, dated February 3 last, stating that "in consequence of the rapid extension of the Meteorological Service of Australasia in connection with the Oueensland Government-an extension which now embraces a large portion of the Western Pacific Ocean, New Guines, and the Malay Archipelago-it has been determined to stop the issue of the large charts which have hitherto dealt with the meteorology of Australasia only, and to issue, instead, in the early future, a weather chart as complete as possible, embracing not only Australasia, but also the regions above indicated," Some charts have already been issued giving the isobaric lines for the region referred to, and extending southwards and eastwards to New Zealand and the New Hebrides. Isobars drawn for 20° to 30° to the eastward of Brisbane must be to a great extent problematical, and in fact this is admitted by the broken lines extending over the ocean The information, to say the least, seems at present insufficient for the purpose, and over large tracts it is absolutely wanting ; but the establishment of stations in remote islands is, of itself, very desirable.

THE other day Prof Vambery delivered in Edinburgh, under the auspices of the Royal Scottish Geographical Society, an interesting lecture on British civilization and influence in Asla. He had many pleasant things to say about England, but did not quite overlook her shortcomings. He said he was immensely struck by the indifference shown by the public at large to everything that concerned Asia. He had lectured in more than 20 towns in this country, and found, even amongst the middle classes, great ignorance in regard to Asiatic geography and ethnography. Assatic languages, moreover, were greatly neg lected. Germany, which had not got any territory in Asia, bestowed far greater attention upon the old world than this country. He opined that if the interest in Asia would increase in this country commensurately with its political power and influence over the various races in Asia. Britain would decidedly remain there a permanent Power which could never be ousted by any rival He thought that there ought to be more schools for Oriental languages in this country. There was a general supposition that Britons in general could not learn foreign languages, but that was not true. The greatest linguists of our age had been British, as, for example, Lord Strangford for Turkish, and the late Sir Richard Burton and the late Prof. Palmer for Arabic Then there were scholars like Sir James Redhouse, Sir Henry Rawlinson, Sir William White, and many others bearing evidence of the brilliant linguistic capacity of the British He believed that nothing could be easier than to recruit in this island a goodly number of Oriental linguists for employment in various Asiatic countries.

A PAPER by Mesan. G. F. Harrs and H. W. Burrows, on the Econes and Oligocene beds of the Paris Bain, is to be assued as a separate publication by the Geologust' Amonation. It will be illustrated by a map and sections. The paper is the result of several years' careful study of the Parisan Tertianes, and close communication with many eminent French geologists. The suthorn give an elaborate appendix, consisting of a list of the fostial Mollucia, some 3500 species, showing the range in

ume; the nomenciature of each species has been critically revised and brought up to date. Careful attention has also been paid to the relationship between recent and Territary forms. The generic names under which most of the shells are still known in this country are added as an assistance to the student.

Tits Physical Society of London has published the first part of the elements housen of its Proceedings. Among the contents are notes on photographs of rapidly moving objects, and on the culcilating electric part, by Mr. C V. Boys, a formula for calculating approximately the self-induction of a cod, by Prof. John Perry, a lecture experiment illustrating the effect of heat upon the magnetic susceptibility of meka, by Mr. Shelford Perry and Components of the Code of the Co

A I ECTURE by Prof. A. Macalister, delivered on January 29, on the opening of the new anatomical lecture-room at Cambridge, has been published by the Cambridge University Press The subject is "The History of the Study of Anatomy in Cam-

MESSES. CHARLES GRIFFID AND CO. have published the eighth annual issue of the "Year-book of the Scientific and Learned Societies of Crest Birnain and Ireland." The work is compiled from official sources, and comprises lists of the papers read dung 1890 before Societies engaged in fourteen departments of research, with the name of their subtract.

THE Engineering Company, publishers, New York, are issuing a new monthly magazine, entitled Engineering, which is to be wholly devoted to the record of industrial progress. The first two numbers have been published

TREER are some valuable morphological notes in the Johns Hopdins University Circulars for May Among other papers we may mention one on the structure and development of the gonophores of a certain Spishonophore belonging to the order Auronestic (Haeckell), by W. K. Brooks and E. G. Conklin. Other papers are, preliminary notes on some new species of Squills, by R. P. Bigelow, and a preliminary note on the nationary and transfer mation of Torantis. by T. H. Moreyn.

Tute "Bibliothèque Évolutioniste" is the general tuile of a new sciennific series which is being published in Paris. The editor is M. Henry de Vangny. The first volumes are mostly translations, Wallace's "Darwinsma" opening the list, but French authors are also to continue, and works are being prepared by Mearis. A. Sabatier, of Montpellier; J. Deniker, the well-known authoropologist, Prof. Girard, and other

A NEW and very boundful silver mineral a described by Mr. A. Genth in the May number of the American fournal of Science. It was discovered by Schor Aguilar, of the San Carlos Stave Mines at Gausanjanto, Mexico, and has been named after him, aguilatite. It is a sulpho-selenide of silver, of the composition Agg3+ Agg5, the analyses of pure crystals agreeing exactly with this formula. The crystals are into-black in colour, and possess a most brilliant luster. They belong to the cubic system, and consist of carloss shelten dedecahedrons, the edges of which are perfore, while the centre of the faces are frequently elongated its such a manner trace demonstration of the composition of the compos

cakine, which may readily be removed from them by means of dilute active and, frequently a little quarts as associated with them. The crystals are readily sectile and malleable, and their handness is only a 5. Their specific gravity is 7.956. When heated in an open tube to low redness, gradually increasing to heated in an open tube to low redness, gradually increasing to heated may obe the silver, together with a slight insulation of selemina, and stender needles of selemina subhanace of the silver, and stender needles of selemina subhanace of the silver, and stender needles of selemina subhanace of the silver, and stender needles of selemina subhanace of the silver, and stender needles of selemina subhanace of the silver, and stender needles of selemina which has the former subhanace of the silver, and the silver subhanace of the silver, and the silver subhanace of the silver subh

SEVERAL of the simpler sulphides of the organic radicles have been found to occur naturally in the crude petroleum oil of Ohio by Messrs. Mabery and Smith, who describe the mode adopted for their isolation in the current number of the American Chemical Journal As far as they are aware, these alkyl sulphides have never previously been found in nature. When the higher boiling fractions of the distilled oil are agitated with oil of witrad, these sulphur compounds are taken up by the sulphuric acid, and, upon subsequently neutralizing the acid solution with slaked lime, unstable calcium salts are obtained. which are readily decomposed by distillation in steam, which carries over the sulphides without decomposition. By employing these reactions upon a large scale, and afterwards subjecting the mixed sulphides to a rigorous fractional distillation under reduced pressure (150 mm, being the most convenient working pressure), the following sulphides have been isolated, methyl sulphide, (CHa),S; ethyl sulphide, (C,Ha),S, normal propyl sulphide, (C.H.) S; normal and iso-butyl sulphides, (C.H.) S. amyl sulphide, (Caller) S, hexyl sulphide, (Caller), S, and a few other sulphides of mixed radicles Most of these sulphides were obtained in the pure state by treating the products of the fractionation with mercuric chloride, and thus obtaining crystals of the addition compounds of the type (CHa) S HgCl, and subsequently decomposing these crystals of the mercury compounds with sulphuretted hydrogen.

THE additions to the Zoological Society's Gardens during the past week include a Barbary Ape (Macacus innus 6) from North Africa, presented by the Rev. G H Watkins . a Diuca Finch (Disca grisca), two Gay's Finches (Phrygilus gays) from Chili, two De Filippi's Meadow Starlings (Sturnella defilippi) from La Plata, presented by Mr. Charles G Sharpe, two Bankiva Junele Fowls (Gallus bankrea & 9) from India, presented by Captain George James, a Common Rhea (Rhea americana) from South America, presented by Mr R. P. Houston; an Algerian Tortoise (Testudo mauritamea) from North Africa. presented by Mrs Margaret Clarke, a Black eared Marmoset (Hapale pensestlata) from South-east Brazil, presented by Mr. Aubrey Lace, a Capybara (Hydrocherus capybara), a Brown Milvago (Milvago chimango), a Violaceous Night Heron (Nycticorax violaceus) from South America, two Blue bearded Jays (Cyanocorax cyanofogon) from Para, four Crested Screamers (Chauna chavaria) from Buenos Ayres, deposited, two Variegated Sheldrakes (Tadorna varieguta) from New Zealand, two Larger Tree Ducks (Dendrocyena major) from India, purchased, two Japanese Deer (Cerous sila & ?), a Chinchilla (Chinchilla langera), an African Wild Ass (Equus taniopus), born in the Gordens.

OUR ASTRONOMICAL COLUMN.

THE DRAPER CATALOGUE OF STELLAR SPECTRA.—Vol axvii of the Annals of the Astronomical Observatory of Harband Callege contains a catalogue of the spectra of ro, 351 stars, nearly all of them north of the parallel of declination — 25, photographed with the 8 inch Bache telescope. As the work forms a part of the Henry Draper Memorial, it is suggested that it be designated as the Draper Catalogue. In order to produce the spectra, a prints Suckes square and having a refracting angle of 37 was fasteded in front late to the carrier and the state of 37 was fasteded in front late to the carrier and the state of 37 was fasteded in front late to the carrier and the state of 37 was fasteded in front late to the carrier and the state of 37 was fasted in the carrier and the state of 38 was fasted by the letter A to Q. Of these, A, B, C, and D indicate to the carrier and the state of 38 was fasted in the state of 38 was fasted in the state of 38 was fasted in the letter P is reserved for planetary nobular. SOLAR OBSERVATIONS FROM JANUARY TO MARCH 1891.— In Comptes rendus, No. 19 (May 11, 1891), Prof. Tacchini gives the following account of solar activity during the first three

months of this year. Observations of spots and faculæ have been made on 64 days, viz. 16 in January, 26 in February, and 22 in March The

results obt	ained are i					
	Relative frequency		Relative magnitude			Number
1891	of Spots	of days	of apote	of facular.		groups per day.
January February	. 1.56 . 2.3t	0 30 O 15	18″50 24'04 .	16 88 89 62		1*38
March	1'27	0'14	ti gt	4t 82		1'45

The following are the results of observations of hydrogen prominences '--

28gz	Number	Prominences			
	of days of observation	Mean number	Mean height	Mean extension	
January	13	4 62	36 ["] 9	1,3	
Fehruary	22	7.55	44 I	1.8	
March	. 17	6 t2	40 1	1.2	

When these numbers are compared with those obtained for When these numbers are compared with those obtained for the last three months of 1890, a marked increase is apparent. In addition to this the results obtained for spots, faculte, and pruminences indicate that a secondary maximum of solar activity occurred during the month of February.

ACTIVITY Occurred quering the month of February.

ANIMAL LIFE ON A CORAL REEFS

IN nearly all the shallow waters of the tropical seas there is an abundant fauna, but nowhere is there such a crowd of marine animals of all kinds as there is in the region that extends manne animals of all kinds as there is in the region time extends from the growing edge of the coral reef to a depth of some to or 15 fathoms beyond it. This may be due to the fact that in this region there is plenty of light and heat, no great or sudden changes of temperature, or of the chemical composition of the water, and there is an abundant food supply brought by tidal currents from the surface of the ocean. Here it is, then, stall currents from the surface of the ocean. Here it is, then, that we find the richest fauou. Here it is that the struggle for existence is most severe, and here it is that the animals are protected and concealed by the most pronounced marks and colours, and provided by Nature with various forms of amourt, stings and spines to defend them in the battles with their cremises.

One of the most interesting results of this severe struggle for Abstract of Lecture by Dr S. J. Hickson, delivered at the London Institution, January 22, 2841.

existence, or perhaps it would be more correct to say of the large number of species competing for existence, is the important faunistic difference that may be observed between one reef and -nay, indeed, between one part of a reef and another part of the same reef.

smother—say, indeed, between one part of a reef and another part of the same reef.

Darwin long ago pointed out that in the straggle for existence svery slight deviating gained by any one of the competing follows that a very slight though constant difference in the physical conditions, such, for example, in the case of coral reefs, as rapidity of tidal currents, amount of surf or character of the physical conditions, such, for example, in the case of coral reefs, as rapidity of tidal currents, amount of surf or character of the family. The real reef is the surface of the surface of the family of the constant of the surface of the family of the constant of the family of the constant and reference in the family of the constant and refound on the reefs of North Celebes belong to two great orders—the Zoansharas and Agyonaria. The prevaling color of the Iving Zoansharas some cases the growing or younger branches as a whole, may be very highly coloured. White, pink, emerald green, violet, and blue, are colours frequently met with in different parts of the Zoansharas notdown. The surface of the violet parts of the Aleyonaria. The tentacles of the polygo of Tubpora, for the Department of the constant on the colour of the stop parts of the Aleyonaria. The tentacles of the polygo of Tubpora, for the bown. A species of Sarcophytum, spain, common on the shores of Celebes, showed green and greenshyellow and yellow samples within the same half-mile of reef. All of these coal colours, with the exception of the colour on the shores of Celebes, tho wed green and greenshyellow and yellow samples within the same half-mile of reef. All of these coal colours in this study, also become in the study of the colour of the spicules mentioned (longed immention in this study, also bown. above, are soluble in spirit, the soft parts becoming, after pro-longed immersion in this fluid, pale brown. The alcohol extracts of a considerable number of corals have now been

extracts of a considerable number of corals have now been submitted to spectrum analysis, and the bands they exhibit show consistency and the same statement of the colours of the corals are experimental evidence as present that proves that he colours of the corals, nor, indeed, of the sponges, are extended to the protective or warning infunction. It seems much more probable that these brilliant colours represent different stages in the building.

that these brilliant colours represent different stages in the building up or breating down of some complex chemical substance that up to restain the stages of the stages and those of them that seem to live habitually among the corals of the reef are characterized by the possession of very curious

of the recei are characterized by the possession of very curious spots or attripes and very brillant colours. Soon after my arrival in Talisse a large lobster was brought to me marked by broad transverse bands of blue and white, a large Squilla is not uncommon marked with aimlar bands of white and deep purple, and the little prawn Stenopus hispidus, that I found in a tidal pool close to a reef, has bands of red and that I found in a tidal pool close to a reet, has bands or red and white. The cephalopods have also peculiar markings. One specumen that I found, Octopus: lianulaiss, had large blue spots over its body and arms. The fishes, again, are marked with spots and stripes of various kinds and many brilliant colours.

Without going too deeply into the argument, we are justified in saying that these animals are so marked and coloured because in saying that these animals are consisted and coloured because they live among the billiant surroundings of the couri level, or, to put it in another way, animals similarly organized and of similar habits would be at a disadvantage on the coral refs if they were not so marked and coloured. The other fashes of the test of the consistency of the consiste the surroundings.

Most of the colours must be considered to be concealment

NO. 1126, VOL. 447

colours Stenopus hispidus, though so very conspicuous when colours Stranger Inspiritus, though no very compresses when taken out of the water, was extremely difficult to see in the pool where I found it is about, in all probability have finished to within y take I found it is a substantial to the property of the that are coloured blue are much less readily seen than the gold, yellow, and red varieties, but an examination of the fish that I yearow, and rec variences, not an examination of the mai that it caught myself, and were caught for me by the natives, showed that the fish in which blue is the prevailing colour are much more frequent in the very shallow water, while those that were caught in water from 15 to 20 fathoms were more frequently red or yellow. The blue colour scems to be a protection for the caught in water from a constraint of the fish from air-breathing enemies—the eagles, ospreys, and hawks—and as these enemies can only approach them from above, the colours are frequently confined to the dorsal sides. The red and yellow colours of the fish seem to be a protection from animals, such as the sharks, perch, and other carmovorous fish, that approach them from the deeper waters beyond the reefs. Thus red and yellow fishes rarely have these colours confined to the upper sides, and many of the blue fishes are coloured red or

yellow ventrally
It is difficult to frame any general rule to account for the It is difficult to frame any general rule to account for the curious distribution of the colours of these animals in spots and stripes Speaking in very general terms, for there are many executions, the fit hath browse on the cornis, possessing small fish, and Surgeon), are striped, those that feed on other fish, and have large months armed withfearmiverous teath, such as the Sermaldie, are aported. The only examined of what appears to be a strange colour that the striped of what appears to be a strange colour that the striped of what appears to be a strange colour that the strange colour than the strange colour that the strange colour that the strange colour that the strange colour than the strange colour that the strange colour that the strange colour that the strange colour that the strange colour than the strange colour than the strange colour that the strange colour than the strange colour than the strange colour that the strange colour than the st

I have noticed occurs in connection with the spines on the tails of certain Surgeons and Trigger fish Annihurus achilla, for example, has a uniform purple colour, but there is a bright red patch surrounding the formidable tail spines that give these fish the name of Surgeons. Similar warning colours are very pro-nounced also in Nateus unicormis and Nateus lituratus, and in some of the Ballistick

WASHINGTON MAGNETIC OBSERVATIONS.

THIS volume contains the results that have been obtained from the magnetic observations taken at the Naval Obser vatory during the years 1838 and 1859. The instruments which they were made were, in the year 1837, placed in their respective buildings that had been erected for that purpose the Bureau of Navigation. In the construction of these buildings that had been rected for the purpose the surface of the second of the the Bureau of Navigation. In the construction of these buildings the greatest care was taken to insure the complete elimination of local disturbances. No tron or any magnetic material was used at all, and the faxtenings, &c., were entirely of copper, brass, and wood; even the stoves, in which only wood was

hurnt, were of soap-stone, with copper pipes.

The instruments that were employed consisted of a declinometer, theodolite, portable magnetometer, dip eircle, a set of meter, incodoline, portanous magnerometer, dip errore, a set or self-recording magnelographs, a seismoscope, and seasongraph; each of them, with the exception of the last two mentioned, being set on piers based on concrete, and in no way conarcted with the floors of the buildings. To complete the equipment, a compast-tetting stand is placed on a pier north of the theodolite, compast-testing stand is placed on a pier north of the theodolite, and is capable of motion in an east and west direction. By means of an arm carrying two prisms that have adjusting screws, the opposite marks on the compast card can be placed in the field of view of the theodolite when the latter is directed on the prisms. All the observations, which are represented in tabular form, denote the results that have been obtained after applying form, denote the results that have been coltained after applying all necessary corrections. The tables include, among others, the mean hourly values of the horizontal and vertical force for each month of 1889, and of the declination for each month of 1888 and 1889, the last of which are taken from the monthly curves; declination ordinates for each hour, in minutes of are

taken from daily declination traces; hourly values of horizontal "Appendix I -- "Magnetic Observations " By Eusign J A Hoogewerff, U S. Navy. (Washington . Government Printing Office, 1890) NO. 1126, VOL. 44]

and vertical force in absolute measure with all corrections, ob servations of horizontal intensity and dip, with a summary of disturbances in declination which differed two minutes or more

dausthances in declination which disteres two minuses or more from the mean mostly carre. No less important is the series of the fourteen large plates at the end of the volume. The first shows the way that the daily photographic traces of declination, horizontal and vertical forma-photographic reases of declination, horizontal and vertical forma-variation of the magnetic elements for the year 1889. In this latter plate the curve that gives the integration of these elements— — that oversit the mean durant lotal force—fromg out the that is, that gives the mean durnal total force—brings out the fact that in every twenty-four hours there are two maxima and two minima, these latter two occurring between midnight and noon (75th meridian mean time).

Den 1751 meridian mean time).
Plates ni, to vi melusive show the traces of the monthly imposite curves of declination for the two years.

In Plates vis. to xiv most interesting comparison is made of the disturbed days of declination taken from observations at Washington, Los Angeles (California), Toronto (Canada), and Pawlowsk (Russia). the curves are all computed for the same time (i.e. for the 75th meridian west of Greenwich), and reduced to the same length of base line. Although on the whole the to the same length of base line. Although on the whole the urvers show a more or lest equal variation, yet there are some cases in which a decided local variation has taken place. For o'cleck (15th needfant time), the magnetic declination at Washington, Los Angeles, and Toronto, shows only slight variations, Los Angeles, and Toronto, shows only slight variations, Another very interesting case happens on March 17t, when the curves traced at Washington and Toronto are quite similar to echo their, but different from those treed at the other two places: the curve showing the magnetic disturbances in declination at Pawlowsk being very similar to that indicating the horizontal force at Washington

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE,—The subject of the Rede Lecture, to be given by Sir Alfred Lyall on June 17, is "Natural Religion in

The General Board of Studies have again brought forward proposals for the increase of the stipends paid to University ecturers and Demonstrators in Natural Science, which had to

be postponed last year owing to want of funds

Mr. A Hutchinson, Demonstrator of Chemistry in Caius College, has been recognized as a Teacher of Chemistry with reference to the regulations for medical degrees

A Syndicate is proposed by the Council of the Senate for the purpose of considering whether any alternative for Greek should be permitted in the Previous Examination. This is sure to rouse much agitation, but it may be hoped that the long-vexed question will at length be settled in a liberal sense

questions was a tengin no settied in a nortal sense.

Another Syndricate is to consider the office of Superintendent of the Museums of Zoology and Comparative Anatomy, about to be vacated by Mr J. W. Clark, Registrary Some rearrangement of the duties, &c., is considered destrable

THE American Meteorological Yournal for March contains:— An article by S. M. Ballou, on Prof. Russell's theory of cold waves, published in the Report of the Chief Spand Officer for 1889. This article ha report of a paper read at the meeting of the New England Meteorological Society on January 20 last According to Prof. Russell's theory, the cause of the cold area from which the cold wave is drawn is held to be a preliminary strong upward diminution of temperature in the air, a subsequent strong upward dimination of temperature in the air, a subsequent overtaming, bringing the cold air to the surface and producing overtaming, bringing the cold air to the surface and producing producing high pressure. The author points out that each of these assumptions would probably be questioned, and the considers each of them in detail, quoting from the works of the considers each of them in detail, quoting from the works of the considers each of them in a straphyton of the substance of a reply by Dr. Hann, in the Miteorologicals Zuitakryft of September 1890, or the criticism of FPO Hasses. These papers have already been noticed at length in NATURE.

Royal Society, April 30 — "The Passive State of Iron and Steel, Part III." By Thos Andrews, F.R.S. M.Inst.C E Sense V. Set I. Relative Paisonly of Wrought-west and various Steel Bars, and the Influence of Chemical Composition and Physical Structure on their Pairs State in Cold Nation Acid -The passive state of iron or steel may have hitherto been regarded by many as a sort of fixed property pertaining to iron and steel alike, when immersed in cold strong nitric acid. The following experiments were made to investigate if the passivity was of a universally static character, or whether it varied with the chemical composition and general physical structure of the

metal, and, if so, to what extent
The experiments of Series V., Set I, were made on bars of
the various steels selected from the author's standard samples. The bars were cold drawn through a wortle, and were therefore different in physical structure to the rolled plates used in the second series of the experiments. An idea of their general properties will be obtained on reference to Part II, Tables IV. properties will be obtained as the second of their general properties will be obtained for reference to Part II. Tablest IV. Applied VA. Applied badd for reference to Part II. Tablest IV. Of the steel to be tested was placed in the wooden stand will along with a polithed wrought iron bar of equal size, and the pair were then immersed in if fluid ounce of intime cold, with the particular to the part of the particular to the

The wrought-iron bars used in each experiment were cut from one longer polished rod, so as to afford a fair comparison of the relative passivity of the various steels, compared with the wrought iron and also with each other. The results are the

average of numerous experiments in each case.

The experiments of Series V., Set 1, on the relative pa-sivity of wrough 1:ron, soft cast-steel, hard cast-steel, soft bessemer steel, and tungsten steel, showed that wrough-1:ron well-cictor. positive to the steels with a considerable E.M.F., the wrought-iron being thus shown to be less passive than the

Series V, Set 2 Relative Passivity of Wrought-iron and various Steel Plates in Cold Nitric Acid, sp. gr 1'42.—In the following series of observations, the metals experimented upon consisted of plates of rolled wrought-iron, rolled ateels made by the Bessemer, Siemens-Martin, or crucible east steel processes, such as soft cast-steel, hard cast-steel, soft Bessemer steel, hard

Bessemer steel, soft Siemens steel, hard Siemens steel, and they are of the chemical composition given on Table VII. The terms "soft" and "hard" relate only to difference of percentage of combined carbon, and not to their having undercentage of combined carbon, and not to their having under-gone annealing or hardening processes. Each piate was 3 inches square, by anch thick = total area of exposure 195 square inches including edges, brightly polished all over, and had a long thin strip left on the top ude, for convenience of attaching to the galvanometer connections. The whole of the wrength-tron plates, used as elements with the various steel plates, were cut from one larger wrought-iron plate, and were thus practically of uniform composition, thus ensuring an accurate comparison of the relative pas-ivity of the wroughtan accurate companson of the relaire pas-inty of the wrought-ton compared with the different types of steels, and at the same time indicating relatively the influence of varied composition and atractive on the passivity of the different classes of steels under observation. In each experiment, a polished wrought-tion plate and a polished steel plate were firmly placed in two or plate and a polished steel plate were firmly placed in two procession was to be a possible of the place of the plate was then carefully placed clovely over a porciain vested containing. If shull do unces of inter and, sp. gr. 1.42, the plates being fully immersed in the acid, and the portoring whaths of the base connected in circuit with the guivanometer. The electro-chemical effects observed were then Table VIII. and indicated that worcely time was see passive Table VIII, and indicated that wrought from was less passive than the steels, and further demonstrated that steels of a higher percentage of combined carbon are more passive than those of a lower percentage of combined carbon.

lower percentage of combined carbon.

Gmen al Kemarks — It has been necessary to give in modified iteral the effects observed during the pends of experimentation of the effects observed during the pends of experimentation an accurate infinite interest of the research, and a brief résismé of some of the principal results and conclusions arrived at by the author up to the present time may now

e given.

(1) The experimental observations of Part I, Series 1, idicate that the influence of magnetization on the passive state of steel rods in cold nitric acid, sp. gr 1 42, is not very great, but it was detectable with the delicate galvanometer and by the sensitive electro-chemical method pursued by the author in the investigation

investigation

The effect of magnetization is more marked in warm nitro and and when the iron x in a powiered state, as shown in the control of the control

state, magnetized steet part were rather test passave in meaning and than unmagnetized ones

(3) The results in Part II, Series III, show that the passivity of both unmagnetized wrought-tron and unmagnetized steel in nitric acid, sp gr. 142, is considerably and proportionately re nutrie acus, sp gr. 1 42, is considerably and proportionately reduced as the temperature of the acid increases, until the temperature point of transition from the passive to the active state is reached at a temperature of about 195. F, and it was also found that the wrought tron was less passive in the warm nitro-acid than cest-tated (See also remarks at foot of Diagram I. in Part II)

(4) The results of the observations of Part II., Series IV, icate that Scheurer-Kestner was, to some extent, in error in regarding the passivity of iron as not dependent on the greater or less degree of saturation of the acid. The author's experi-ments briefn recorded have shown that the passivity of the metals employed, viz. wrought iron, soft cast-steel, hard cast-steel, soft Bessemer steel, and tungsten steel, was very materially increased with the concentration of the nitrie acid; and it was also observed that wrought-iron was much less passive in the nutrie acid of less concentration than most of the steels, the soft Bessemer steel being found about equal in passivity to the wrought-iron under the conditions of experimentation. A reference to Table III shows that a considerable amount of EMF, was developed between the various metals in every instance, which is a circumstance of much interest in connection

instance, which is a circumstance of much interest in connection with the passive state of ron and steel.

(5) The results obtained in Part III, Series V and VI., on the relative passivity of wrought-iron and the various steels—soft cast-steel, hard cast-steel, soft Bessemer steel, hard Bes semer steel, soft Siemens steel, and hard Siemens steel-are of semer steel, sort Siemens steel, and narn Siemens steel—ale of an important character, showing, by the delicate electro-chemical method employed, the sensitive influence of difference in chemetnou employed, the sensitive influence of difference in che-mical composition and physical structure, &c., on the passive state of the metals. Generally throughout this series of experi-ments it will be observed that the wrought-tron was electro-positive to the steels with a considerable E.M.F., amounting, in some cases, to as high as one tenth to one-seventh of a volt. the wrought from being thus shown to be less passive than the

steels, defence to the experiments in the wrought-iron and various sized plates, on Table VIII. shows that the E.M.Y between the passive wrought-iron and the various soft steels, which contained less percentage of combined earbon, in circuit in cold intre said, sp. gr. 142, was very considerably less than the L.M.F. under similar conditions between the wrought-iron. E. M.F. under similar conditions between the wrought-iron plates and the different hard such saving a higher percentage of combined carbon. The latter results, therefore, demonstrate the interesting crumstance that steels of a higher percentage of combined carbon are more passive than those of a lower percentage of combined carbon. It will be observed that the wrought iron was also electro-positive to most of the steels, whether of a higher or lower percentage of combined carbons. which shows that wrought-iron may be regarded as generally less passive than steels

May 14.—" Researches on the Structure, Organization, and Classification of the Fossil Reptiha VII Further Observations on Pareassaurus" By H G Seeley, F.R.S, Professor of Geography in King's College, London All the affinites Intierto attributed to Pareassaurus with

ally rinthodonts. Anomodonts. Procelephon, and Mammals are Laty nuthodonts, Anomodonts, Procelophon, and Mammals are shown more strongly in the several parts of the skeleton, by the new evidence The shoulder-girdle is more Labyrinthodont than was previously supposed, the skull is more Reputilan, and the pelvis and limbs are more Mammalian, though with some resemblance to Dinosaurs

From furthur evidence of the structure of the skeleton in Procelephon, the author regards that type as a member of the Pareiasauria, rather than as forming a distinct sub order. It also has four sacral vertebrae

The divisions of the Anomodontia are grouped as-

Physical Society, May 9 - The Society varied its ordinary procedure by paying a visit to the ancient seat of learning situated on the banks of the Cam. Assembling at Liverpool Street Station, members and visitors to the number of about one hundred were conveyed in saloon carriages by the II one hundred were conveyed in asloon carrages by the 11 of o'clock express direct to their defentiation, the whole journey o'clock express direct to their defentiation, the whole journey those present were Dr. E. Aklimon, Prof. Ayrton and Mrs. Hukerharton, Mr. Miller Bally, Mr. Sellerde Blasel and Mrs. Blakerlawdl, Mr. D. J. Blakley, Mr. T. H. Blaketley and Mrs. Blakerlawdl, Mrs. Blakerlawdl, Mrs. Blakerlawdl, Mrs. Tranklamd, Dr. W. R. Hodghuson, Prof. O. J. Lodge, Mrs. Frankland, Dr. W. R. Hodghuson, Prof. O. J. Lodge, Frof. Meldolp, Prof. Perry and Mrs. Frankland, Dr. W. R. Hodghuson, Prof. O. J. Lodge, Trof. Meldolp, Prof. Perry and Mrs. Thompson, Mr. A. F. Sumpore, Prof. S. T. Thompson and Mrs. Thompson, Mr. A. F. at the historic town the party became the reuses to the Camrotter and sith. Frotter, and Mr. O. M. whipple. On arriving at the historic town the party became the guests of the Cambridge members, and proceeded to Emmanuel College, where they were received by Mr. W. N. Shaw. Various groups visited the clouters, chippel, and gardens, and at one o'dook tunch was provided in the College Hall At 2. 20, a meeting of the Society was held in the Lecture Room of the Cavendh Laboratory. The papers read were all by sathows resident

in Cambridge, and the abstracts given below will sufficiently indirect the variety of the subjects brought before the Sonety to the control of the control o can be compared; and the new air condensers to be used by Mr Glazebrook as standards The Cambridge Scientific Instrument Company had an interesting exhibit, including a dividing engine, Boys's radio-micrometer, electrically driven tuning forks, engine, Boys's radio-micrometer, electrically driven tuning firsk, and various recording instruments, amongst which was Galton's apparatus for registering the growth of plants. Other things which attracted attention were Glazebrook's spectrophotometer, Lord Rayleigh's coils and apparatus used in his determination of Loru rayengus coust and apparatus used in his determination of the ohm, a collection of models, medals, and instruments, formerly belonging to Prof Maxwell, the resistance standards of the British Association, together with the historic rotating coils and electrodynamometer used in the determination of the BA unit. Tea was served in the Combination of the Trinity College, and a majority of the visitors returned to town Trinty College, and a majority of the visitors returned to town by the 8 o'clock express, greatly pleased with the day's oating. Others, however, prolonged their visit intil Monday, and had opportunities of discussing important physical problems with the Cambridge members. The meeting was in every sense a great success, and will long be remembered as a red letter day in the history of the Society - At the secure meeting, held in the Cavendish Laboratory, Prof Ayrton, F R S, President, in the chair, the following communications were made -S experiments on the electric discharge in vacuum tubes, by Prof J J thomson, F R S The phenomena of vacuum discharges were, he said, greatly simplified when their path was wholly gaseous, the coundication of the dark space surrounding th negative electrode and the stratifications so commonly observed in ordinary vacuum tubes being absent To produce discharges in tubes devoid of electrodes was, however, not easy to accomplish, for the only available means of producing an electromotive force in the discharge circuit was by electro-magnetic induction Ordinary methods of producing variable induction were value less, and recourse was had to the oscillatory discharge of a Levden iar, which combines the two essentials of a current whose maximum value is enormous, and whose rapidity of alternation is immensely great. The discharge circuits, which may take the shape of hulbs or of tubes bent in the form of coils, were placed in close proximity to glass tubes filled with mercury, which formed the path of the oscillatory discharge. The parts thus corresponded to the windings of an induction coil, the vacuum tubes being the secondary and the tubes filled with mercury the In such an apparatus the Leyden jar need not be large, and neither primary or secondary need have many turns, for this would increase the self-induction of the former and lengthen this would increase the self-induction of the former and lengthen the discharge path in the latter forcessing the self-induction of the primary reduces the E.M.F induced in the secondary, whilst lengthening the secondary does not increase the E.M.F per unit length. Two or three turns in each were found to be quie sufficient, and on discharging the Leyden jar between two highly polished knobs in the primary circuit a plain uniform band of light was seen to use young the exhausted bulb containing traces of oxygen was placed within a exhausted but containing traces of oxygen was placed within a primary spiral of three turns, and on passing the jar discharge, a circle of light was seen within the halb in close proximity to the primary circuit, accompanied by a purplish glow which lasted for a second or more. On heating the balk, the duration the glow was greatly diminished, and it could be instantly extinguished by the presence of an electro-magnet. Another exhausted bulb surrounded by a primary spiral was contained exhausted bulb surrounded by a primary spiral was contained in a bell jar, and when the pressure of air in the jar was about that of the atmosphere, the secondary ducharge occurred in the bulb, as is ordinarily the case. On exhausing the jar, however, the luminous ducharge grew fainter, and a point exhausted to the bulb or jar the excondary dechange to appear exhausten of the lar caused the secondary dechange to appear exhausten of the lar caused the secondary dechange to appear exhausten of the bulb or jar the author could only explain on two suppositions, viz. that under the conditions then existing the special inclusive capacity of the gas was very great, or that a dechange could pass without being luminous. The author could be considered that the special caused the passage of the could be considered that the could be considered to th out electrodes sacressed as the pressure diminished, until a certain

point was reached, and afterwards diminished again, the above the temperature of the electrodes. One peculiarity of way due to the presence of the electrodes. One peculiarity of many different peculiarity of the present peculiarity of the present peculiarity of the present peculiarity of the present peculiarity of the peculiarity of t oint was reached, and afterwards diminished again, thus showthe ions, by Mr. W. C. D. Whetham. In studying electrolysis the question as to whether there is any transference of solvent when a porcous wall is absent presented itself to the author. The ordinary methods of testing for transferences, such as by increase ordinary methods of testing for transferences, such as by increase disparages, the surbor used different coloured solutions of the same salt, such as cobal chloride in water and in acholol, the former of which is red and the latter blue. By putting the solutions into the and U-shaped these any tangen in the position of the line of junction of the two liquids could be necessarily recognitions and the same water was the same ware former to the same water to be same water to the same water to be Two aqueous solutions in which the amon was the same were also inted, one combination being cupric chloride and common salt, and in this case the line of demacation traversed about 7 inches in their bours. The results intherio obtained by this method agreed faithy with those found by Kohlmusch—On the reasstance of some mercury standards, by Mr. R. T. Glaze-the reasstance of some mercury standards, by Mr. R. T. Glazethe resustance of some mercury standards, by Mr. R. T. Glassroot, F.R.S. 18 in 1885, M. Benoit, of Paris, supplied the stuhor with three mercury standards, noninally representing the Paris Chopress olm, now commonly homes as the legid olm. Tests and the control of the common standards of the Paris Handward of the Chopress old, and the Chapter of the Chapter of the Chapter old, and and the Chapter old, and That shows that within the limit of experimental error the fusion of the metrory standards to the BA. Acids have remained practically unchanged during air years. The numbers given above are based on Lord Rayleigh's determination of the specific resustance of mercury, which differs appreciably from that found concordant determinations, the values of the mercury standards expressed in legal ohms become (No. 37) 1 00033 and (No. 39) 09995. The values given by the maker were 1 00045 and 0 09954, respectively, showing a very close agreement. The sustine also found that refilling No. 37 from the same sample of mercury produced to appreciable change in its resistance, when ments on the co-efficient of increase of resistance of fusercury with ments on the co-efficient of increase of resistance of mercury with temperature gave the value o 000872 as the mean coefficient between o' and 10° C., a number rather less than that obtained between o' and to' C., a number rather less than that obtained by Kohlrauch —Oa an apparatus for measuring the compressibility of liquids, by Mr. Skinner. The apparatus consisted of a large phenoid flask, with a long narrow neck containing the communication through a stopcock and fleshle tabe with an adjustable reservor. By rasing or lowering the latter the flask could be easily filled or empited or the quantity of liquid dispited. The flash was inclosed in a bell jay, whose interior produced by blowing into the jar caused the liquid to descend about 1 continued to the control of the liask. This movement is the control of the light of the control of the light of the control of the liask. This movement is the control of the liask. This movement is the control of the liask. This movement is the control of compressibility had been tested as different to the control of compressibility had been tested as different to the control of the contro corresponded with a change of volume of about half a millionth. The coefficient of compressibility had been tested at different The coefficient of compressibility had been tested at different temperatures, and the results were not very different from those obtained by Tart and others. The influence of salts in solution great difference in this respect found between electrolytes and non-electrolytes.—Some measurements with the pneumatic bridge, by Mr. W. N. Shaw. The action of the paparates is analogous in many respects to the Wheatstone's bridge, and its object is to comparate the pneumatic resultances or conductivities.

of various orifices, channels, tubes, &c. The proportional arms are represented by two circular holes in than plates of much, the sake by a serve, and the fourth might consist of any aperture or tube whose conductivity was to be determined. The servent apparence are presented by large worden boxes apparence are presented by large worden boxes of the contractivity itself at right angles to the tube when no air current is passing. itself at right angles to the tube when no air current as passing. The apparatus is remarkably sensitive to movement of the abutter, and on starting or stopping the draught after balance that been obtained, effects analogous to those produced by self-abutter, and the sensitive of the self-abutter and the sensitive of the self-abutter of the sel afterwards diminishes with further increase of length. Putting a lange on the outlet and reduces the anomalous effect, while a bevelled mouthpixed similarly placed causes it to disappear. In the discussion on Prof. Thomson's paper, Prof. Privgerald and the beautiful experiments were likely to lead to very improgram to the control of t the write was on the ade remote from the primary, and if there was any great increase in specific innuctive capacity, be would for further information as to the action of the magnet in preventing the after glow, and in some cases precipitaling a luminous ducharge. The experiment with the exhausted bulb may be action of the contract Thomson had tred Mr. Crookes's experiment, in which the electric pressure necessary to produce a duckage was greatly electric pressure necessary to produce a duckage was greatly Prof. Thomson, in reply, said he had not tried the experiment, but the phosphoresence he had observed was of quite a different character from that produced in Mr. Crookes' tubes. To Prof. character from that produced in Mr. Crookes' tubes. To Prof. of the glow, but he believed the glow to be due to a combination which might be prevented or facilitated by the action of the magnet causing the density to be different in different parts of magnet causing the density to be different in different parts or the bulb. M. Guillaume, in discussing Mr. Senner's paper, described the methods used by Sabine, Jamin, and others, in determining the compressibility of liquids, and pointed out their defects. The chief difficulty in such experiments was in finding the compressibility of the reservoir. Numbers expressing the compressibility of mercury obtained by different observers were compressibility of mercury obtained by different observers, were given, the best values avarying between cooccopy and coccope, —On the motion of Prof. Ayrion, seconded by Prof. Rucker, a hearty vote of thanks was accorded to the authors for their valuable and interesting communications, and for the kind manner in which the Society had been received and entertained by the Cambridge members Prof. Thomson and Mr Glazebrook acknowledged the vote

Geological Society, May 6.—Dr. A. Geikie, F.R.S., Freudent, in the chair —The following communications were read—One Rhesio, by E. Wilson. In a deep railway-cutting at Pylle Hill or Totter Down Brisio, by E. Wilson. In a deep railway-cutting at Pylle Hill or Totter Down Gets, are exposed between the Tea Green Maris and the Lower Liax. There is no doubt as to the division between the Rheute and Keeper beds in this section, but the line of demarcation between the Rheute and the Lass has always been a matter of the Common than the Common that the Common than the Common t

Pea Gnt Series		50	'14
Transition Beds		38.3	'13

This shows a great falling off in the percentage of revidue above the Transuton Beds. That of the Freetoness irremarkably ow, and it would appear that these rocks were formed under condi-tions which allowed of very little sediment being deposited. The paper gave rue to a discussion, in which Prof. Hull, Mr Richerdge, Mr, H. B. Woodward, the Rev. H. Wanwood, and the author took part

Royal Meteorological Society, May 20—Mr. Baldwin Latham, Prevident, in the chair—The following papers were read;—On the vertical circulation of the atmosphere in relation to the formation of storms, by Mr. W II. Dines. After giving an outline of the circulation of the atmosphere, the author refers to the two theories which have been suggested to account for the to the two incortes which have neen suggested to account or the formation of somm, viz. (1) the convection theory, which is that the central air ruses in consequence of its greater relative warmth, this warmth being produced by the latent heat set free by condensation, and (3) the theory that the storms are critical eddies produced by the general motion of the atmosphere as a whole, just as small water eddies are formed in a flowing stream of water. The author is of opinion that the coverection theory is the more probable of the two, but more information about the take more probable of the two, but more information about the temperature of the upper are is greatly needed.—On Brocken spectres in a London log, by Mr. A. W. Clayden During the dense fogs in February last, the author made a number of experiments with the view of rasing his own spectre. This he ultimately succeeded in accomplishing by placing a steady himself in the control of the second of the form of the them made some careful measurements of the size of the first first them made some careful measurements of the size. and distance of the spectre, and also succeeded an taking some photographs of the phenomenon.—An account of the "Leste," or hot wind of Madeirs, by Dr. H. Coupland Taylor. The "Leste" is a very dry and parching wind, sometimes very hot,

blowing over the usland from the E.N.E. or E.S.E., and corresponds to the sirectoof Algera, or the hot north winds from the deserts of the interior experienced in Southern Australia. Grant of the control of the contr Shelford Bidwell, F.R.S., exhibited an experiment showing the effect of an electrical discharge upon the condensation of steam. The shadow of a small jet of steam cast upon a white wall's, under ordinary conditions, of feeble intensity and of a neutral tut. But if the steam is electrified, the density of the shadow titl But if the steam is electrified, the density of the shadow is at once greatly increased, and it assumes a peculiar orange-brown hue. The electrical discharge appears to promote conclusions of the exceedingly municiparticles of water continuous control of the more refinagible rays of light. It is suggested that this experiment may help to explain the intense dischesses, offen tempered by a lurid yellow glow, which is characteristic of thunderdoolds.

Linnean Society, April 16.—Prof Stewart, President, in the chair,—A paper by the Rev. F. R. Wilson, was read, on lichens from Victoria, in which several new species were described, ischess from Victoria, in which several new species were described; specimens of which were exhibited.—A paper by Surgeon-Major specimens of which were exhibited.—A paper by Surgeon-Major viz. P. cormate, Corda, and a new species which the author proposed to name P. Jammi-chryptogeon. A feature of peculiar interest noted in the latter species was the extra-ordinary abundance and wide distribution of the teleutopra-ordinary abundance and wide distribution of the teleutoprastage as compared with the comparative scarcity of the acidial

suge a compared with the comparative variety of the excitate stage, and this disproportion in the distribution of the two stages had been remarked by the author long before he had accretained that they were related. A discussion followed, in which several of the botanist present took part — Poof. B. J. Anderson exhibited a panoranic arrangement for duplaying drawings at biological fectures.—Mr John Young exhibited a nest of the Bearded Timouse (Cadamphilas harmura), which had been built in his aviary Several aggs were laid, but none extend speciment of a Cooklears from Ben Mone, believed to be undescribed — Mr Robert Deane forwarded for exhibition a plant of the Rayless Dany, found growing abundantly in the neghbourhood Carrilli 3 and an undetermined Sponge, dresigned in about, of fathoms, of the coast of South Wales—Mr D. Locast of Devonshire Although figured so long ago as 1640 by Classias, and whalequently noticed by opher observers, the plant coast of Devonshure Although hyured so long ago as 1640 by Classis, and subsequently noticed by other observers, the plant yielding it had only lately been identified by Mr. J. H. Hart, of Trainfad, as Scapellett amazonica Mr. Morris likewise exhibited specimens of the fruit of Catastiemma fragrans, received for the first time, from St. Vincent, showing its rure position to be amongst the Macazos, tribe Bombacas—Mr. Thomas Christy exhibited some Kolis nuts, and made remarks on the Christy exhibited some Kola nuts, and made remarks on the properties attributed to their medicinal use.—A paper was then read by Mr Malcolin I awrie, on the anatomy of the genera Therypetus and Stimonia, and their relationship to recent. Aradinida. An interesting discussion followed, in which the Preadent, Prof. Howes, Dr. H. Woodward, and others took

Entomological Society, May 6,-Mr Frederick DuCane Entonomorgical Society, May 0.—mat Frederick Dulcane Godman, F. R.S., Preiderick, in the chair.—Dr. D. Sharp exhibited a number of eggs of Dylissus marginalis laid on the sheath of a species of reed, and commented on the manner of their owposition, which he said had been fully described by Dr. Regmbatt —The Rer. A. E. Eaton exhibited a collection of Psychodida from Somersetshire, including six species of Psychoda, eleves species of Personna, and one species of Ulwayra Mr. McLachan commented on the interesting nature of the ethibation—Mr. P. Crowley exhibited a specures of Politic soft batton—Mr. P. Crowley exhibited a specures of Politic soft of another equally handromes species of the same grams from Tongshou, Bermanh, which was said to be undeseribed.—Mr II. Goss, the Secretary, read a letter from Mr. Merrideid, pointing Society on April 1 last, of his views on the effects of temperature in causing variation in Depolopera, was incorrect; he (Mr. Merrifield) had never suggested what maght happen to Temperature in Causiniti, and had expressly sitted that he had eleven species of Personna, and one species of Ulomyia

found a reduction of the temperature below 57° to produce no found a reduction of the temperature below 57" to produce no effect, whereas in Mr Fenn's experiments the temperature must have been below 40"—The Secretary also read a letter which Lord Waisingham had received from 51" Arthur Blackwood, the Secretary of the Post Office, in answer to the memorphy which, on behalf of the Society, had been submitted to the which, on behalf of the Society, had been submitted to the Postmaster-General, saking that small parcels containing scientific specimens might be sent to places abroad at the reduced rates of postage applicable to packets of bond fide trade patterns and samples. The letter intimated that, so far as the English and samples. The letter intimated that, so far as the English Post Office was concerned, scientific specimens sent by sample post to places abroad would not be stopped in future.;

THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

THE progress of bacterological scenece, and the amount of exact information which it has shed upon the problems of disease during the last fifteen years, have led several of the Governments of the Content and America to establish institutes providing for original research, as well as technical instruction, in preventive medicine

This country, on the other hand, which pioneered sanitary science from its birth, has, strangely enough, been distinctly behindhand in the study of bacteriology (fraught as it is with interest of such vital importance to the health and prosperity of the nation), and of the provision of institutes of the kind which have been established abroad, such as the Pasteur Institute in Paris, the Hygienische Institut in Berlin, Konigsberg, Breslau, Wiesbaden, St Petersburg, Moscow, Odessa, Tiflis, Warsaw, Cracow, Naples, Turin, Rome, Milan, Palermo, Malta, Barcelona, Constantinople, Bucharest, Budapest, Rio Janeiro, New York, Washington, we have no example in the United Kingdom. In these institutions, the study of the morphology, biology, physiology, and chemistry of micro-organisms, whether pathogenic or not, is being actively pushed forward, and a thorough analysis of their subtle influence as causative factors of disease pursued

In this manner the poisons of the following maladies, the effects of which are among the direst evils to humanity, viz. pyæmia, anthrax, erysipelas, septicæmia, glanders, tubercle, diphtheria, &c , have been isolated, and discovered to be micro-organisms which are now known certainly to be the active principle of the virus When we reflect that, for centuries and centuries, the crippling effects of cpidemic and devastating diseases have been only too well known, but attributed to the operation of all manner of causes, er. supernatural agencies, Divine wrath, meteorological and climatic influences, &c, &c, the fact that the real truth concerning the nature of their causes has been ascertained only within the last few years by laboratory research is, in itself, overwhelmingly expressive of the immense value of Bacteriological Institutes and their work

But their value does not stop here. Knowing, as thanks to bacteriology we now do, the origin of these diseases, it may be asked what has the same science done towards stamping them out and preventing their development, or haply arresting their progress should they unfortunately gain access to, and invade, the tissues of the body To express ourselves more plainly, the question might be put in this form, "What has bacteriological science done to discover the antidotes of such poisons?" The answer is, that whereas centuries of clinical observation have done very little indeed-by watching the sick and the employment of drugs-towards the direct arrest of the virus of infective maladies, laboratory work, on the other hand, has already provided us, not merely with many invaluable and additional facts to general science on the subject of immunity, vaccina-

NO. 1127, VOL. 447

tion, a.e. protection before infection, resistance of tissues to invasion by parasitic organisms, &c.; but has given to medical science, what no pharmacopous has ever been able to do—namely, chemical antidores which by their specific action upon their use of diseases alone successfully save human beings as well as the lower animals from death and incapacitating illness.

Of these new methods, perhaps the most noteworthy is Pasteur's treatment of hydrophobia, but others have been already discovered, and are being examined and tested for practical employment in medicine and surgery

À large institute of this kind, however, is not reserved solely for the investigation of the problems of disease—on the contrary, it has a far wider sphere of usefulness Bacterology, which Pasteur showed was the key to the secrets of fermentation, is, of necessity, all-important to many very extensive trades and commercial undertakings. The botanical and biological researches of the Pasteur Institute are thus to a large event utilized by the Fiench manufacturers, as well as by those of other countries, to their great profile.

The particular bearing of this branch of science has never been fully comprehended by the public, who are not aware what an enormous debt of obligation they owc to M. Pasteur, and to the extension of scientific research. which received its impetus from his genius, and which lias resulted in so much direct gain and benefit to the community In like manner, to agriculture, the questions of clianges in soils-such, for example, as nitrification, now known to be due to the action of micro-organisms-are not less important, and indeed essential A Bacteriological Institute, therefore, has in agriculture, quite apart from the subject of diseases of animals, a fertile source of work of the utmost value and assistance to practical men. But, in addition, there has of later years arisen a branch of chemical industry directed towards the synthetic production of numerous substances which prove to be powerful drugs. The knowledge of these is, of course, incomplete and dangerous until thorough experimental investigation of the action of these substances has been made In this country, however, our chemists are precluded, by the harassing legislation under which their coworkers in physiology, pathology, and medicine labour, from pursuing this useful line of research, without great trouble and endless restrictions, although such work is solely directed towards the therapeutic relief of disease and suffering

The chemistry of disinfection offers in itself an extensive field of research which can alone be cultivated in an institution of this kind reserved for bacteriological investigations.

Lastly, in such an institute two subjects of general interest receive special careful attention. These are (i) the technical instruction of medical men, health officers, chemists, and manufacturers, in bacteriology, both in its morphological and biological aspects; and (2) the examination of tissues and substances suspected to be seat or vehicle of infectious diseases and submitted for investigation and report. The functions of a Bacteriological Institute, therefore, clearly involve interests of the bighest national as well as particular or individual import.

Since the formation of the Pasteur Mansion House

Fund, which has provided for the treatment in Pais of many English sufferers from the bites of rabid dogs, some of the members of the Committee of that Fund, as well as of the Mansion House meeting at which at was inaugurated, knowing the importance to the community of having a similar institute in Great Britain determined to make an effort to establish the state.

A survey of the conditions under which hacteriology is practised in Great Britain is sufficient to show at once the pressing need of creating a centre of the kind, since, although several medical schools and Universities have provided for the teaching of bacteriology to a degree suitable for diplomas in public health medicine, and although in the laboratories of the College of Physicians and Surgeons in Edinburgh, and of the conjoint London Colleges, besides those of University College, King's College, and the College of State Medicine, there is room and provision for a certain amount of original work, still it is quite notorious that the majority of original investigators are driven to go to Paris and Berlin, not only on account of the splendid collection of material and freedom of experiment there, but also for lack of sufficient accommodation in the laboratories of the United Kingdom. To remedy this state of things, and to provide an establishment which would greatly assist the medical schools and technical education generally. is therefore the object of the promoters of the British Institute of Preventive Medicine lopment of the scheme has now arrived at a very interesting point, which, as usual in this country, resolves itself into a contest between the friends and enemies of science. The object of the Institute being purely charitable and scientific, it was from the outset necessary to give its constitution a firm basis, in order to obtain the confidence of the public from whom naturally the cost of creating the Institute is to come. It has therefore to be incorporated, and such incorporation can practically only be obtained by permission of the Board of Frade, which grants leave for the registration of such institutes as limited companies, the word limited being omitted, thus insuring the appropriation of the funds for none but purposes identical with the original object for which they were intended The Executive Committee of the British Institute, therefore, made through their solicitors, Messrs Hunter and flaynes, the formal application for such registration to Sir Michael Hicks Beach. the President of the Board of Trade To their surprise Sir Michael refused to register the Institute, and this without assigning in his letter any reason for his refusal. It is, however, understood that he has done so in consequence of his having received petitions from a few bodies of anti-vivisectionists, among whom are to be found as usual certain names, mostly ecclesiastical, of gentlemen whose mientions, however admirable, are dictated by absolute ignorance of the questions which they presume to discuss

We understand (though it is incomprehensible how a funister should have allowed himself to be placed in such a false position) that Sir Michael Hicks Beach alleges privately that by registering the Institute, a portion of the work of which will naturally include experiments on animals, he will be encroaching on the duties of the Home Office, to which department alone, he ever, as a

matter of fact, is intrusted the administration of the utterly incompetent and harasing so called Vivisection Act. Nothing can excuse the confusion of mind or ignorance which is thus displayed by an offician of the Government, for, as is evident to the merest tyro in law, the question of experimental science has nothing whatever to do with the matter submitted to the Board of Trade, That body has only to make sure that the funds of the Institute cannot in the future be misappropriated to any other object. That is all it is asked to do, and that solely in the interests of the oublife.

The official seal of the Board of Trade having thus been given to stamp the Institute with the character designed for it by its promoters—namely, that of a character character and not a commercial undertaking—it would then, of course, be necessary for the Executive Committee to apply to the Home Office for the registration of the Institute as a place where experimental science may be carried on

With this second registration the Board of Trade has nothing whatever to do, and by taking upon himself the duty of considering this part of its constitution, the President has gone out of his way to raise difficulties in the formation by private individuals of a National Institute, which in other more intelligent and far-seeing countries the Governments have hastened to take the initiative in establishing and liberally supporting

It is evident that Sir Michael Hicks Beach has been greatly misinformed on this matter, and we look forward with interest to the result of the representations of a very powerful deputation which we learn is to wait upon him on Friday, June 5, at 11 a m, and which, constituted a sit is of dissinguished men in all branches of science, as well as of those of the general public who are interested in philanthropic sanitary measures, will point out to him the real facts of the case on which he has to adjudicate, the state of the case on which he has to adjudicate, but the support of the sup

It is not difficult, we believe, to read between the lines in such a case as this No beings are more human than Ministers and members of Parliament, or, in fact, all those whose own position or that of their party depends upon popular clamour Such unfortunates listen like Eve with a fatal fascination to the voice of the deceiver. but, with a taste less worthy than hers, the fruit which attracts them is not that of the tree of universal knowledge, but of the ballot-box They have hitherto laboured under the mistaken impression that an energetic and noisy group of agitators, leading in their train a few unscientific quasi-public men, were an important political body, and they consequently sacrifice to their misrepresentations the liberties of science and the good of commerce. The day is coming, or is rather come, when the scientific and cultured world will refuse to submit any longer to such a condition of affairs, and when all its branches, physiologists, agriculturists, chemists, engineers, medical and legal men, will unite in a compact body for the protection of their common interests, and we rather welcome the present difficulty, which has served to bring prominently forward the spirit animating them, and which no administrator will do wisely in failing to recognize.

THE GEOLOGY AND PHYSICAL GEOGRAPHY
OF NORTH SYRIA.

Grundunge der Geologie und physikalischen Geographie von Nord-Syrien Von Dr. Max Blanckenhorn Mit Zwei Karten, &c. (Berlin: Friedlander, 1891)

N this excellent treatise the author presents the reader with a synoptical view of the results of his observations over a region but little known; referring to his previous essays on the geology, palæontology, and petrology of North Syria for fuller details. The region described extends from the northern slopes of the Lebanon to those of the Taurus Mountains, and from the Mediterranean coast to the banks of the Euphrates and the runs of Palmyra, embracing an area of about 45,000 square miles It also includes the whole of the Orontes Valley and the Kurdish Mountains. The mountainous tracts immediately to the south have already been ably described. as regards their physical structure, by Carl Diener, in an essay which was favourably reviewed in NATURE at the time of its publication in 1886, and these observations on the geology of the Lebanon and Hermon have been taken up and extended by Dr. Blanckenhorn to the horders of Asia Minor Still further south, we have the geology of Palestine illustrated and described by Fraas, Larter, Tristram, and the officers of the Palestine Exploration Fund, extending into Edom and Moab and the Sinaitic peninsula; so that, as far as it is possible for travellers to carry out such a work as that of the geological portraiture of the region, we have now the who'e tract from the shores of the Red Sea to the Taurus Mountains very fully described and illustrated. Two maps on a large scale, one showing the topography, the other the geology, accompany the present work. That there should be uncoloured spaces at intervals in the latter was inevitable. and is a proof of the caution exercised by the author in its preparation. The text itself also contains numerous geological sections and illustrations

In comparing the geological structure of the Lebanon, as described by Diener,1 with that of the range between the valley of the Orontes and the coast, called Djebel Ansarige (Nusairier-gebirge), the author observes that the representatives of the Upper Jura and Cenomanian lying at the base of the Lebanon formations are absent in the more northerly tracts, the lowest beds of the series being represented by the "Rudisten-kalk," of probably Turonian age The engraved longitudinal section which the author gives to illustrate this, amongst other physical features, is drawn from the coast at Latakia (Ladikue) over Dj Hassan Erai to the Orontes at Mischalum, and is of much interest as illustrating the general structure of this part of Northern Syria. The valley of the Orontes is shown to be in the line of a great fault, or system of faults, by which the Eocene limestone beds are "thrown down" along the eastern side of the valley against the older Cretaceous strata, which are elevated into the ranges of Dj. el Ansârije and Hassan Erai, capped by the same Eccene limestones which form the bed of the Orontes, but at a difference of relative level of about 1600 feet. On the eastern side of the valley the Eocene strata risc into high ridges, partly by the aid of a N.-S. fault, which is not im-

4 "Libanon, Grundlimen der phys Goographie u. Goologse, v. Mit e'-

probably a continuation of the "great Jordan-Arabah fault," which has produced such remarkable effects in connection with the physical structure of Palestine and Arabia Petrea.\(^1\) The position of this fault seems also to be indicated in the section across the Oriontes at Hamman Shekh has illustration the region of Mons Cassius.

The author gives a graphic description of the gorge of the Orontes in the neighbourhood of the hot springs (Hammam) above the great bend which the river takes from its northerly course towards the west in order to reach the Mediterranean At Dusr esh-Schoghr the river enters a cañon which has been worn down to a depth of 160 metres in beds of Eucene hujestone and marble rich in Nullipores, and amongst the massive Miocene limestone (Grobkalk), while to the left rises the plateau of Di el Koseir, breaking off in successive terraces towards the Orontes Valley, and on the right the crest of 1)1 el 'Ala On leaving this gorge the river enters an extensive alluvial plain, making a inagnificent sweep round to the westward . and in its course through a rocky and broken country bathes the runed walls of Antioch, the once famous capital of Syria-a city which bears so honourable a place in the early history of Christianity

The region of Northern Syria physically divides itself into three distinct regions which are adopted for purposes of description by the author. The first includes the coast ranges, the second, the depression lying to the east of these, including the valleys of the Orontes and the Kara sea and river, the third, the "Hinterland," or interior tracts of North Syria lying to the east of the depression. and including the Khurdish Mountains, we can only here specially notice this last. This region is remarkable for the great tracts of Miocene strata, reposing sometimes on those of Eocene, sometimes on those of Cretaceous, ages of the Palmyrene wilderness and of Anti-Lebanon, and which are in turn largely overspread by great sheets of plateau basalt Of these Miocene strata the plains round Aleppo are chiefly formed. Here they are nearly horizontal, but towards the north they are tilted, and the Eocene and Cretaceous strata again rise to the surface and terminate in the escarpment of Kardalar Dagh. beyond which rises the high plateau of Kawar, and still further towards the north-west the lofty ridge of Giaur Dagh, which reaches an elevation of 1330 metres This latter is formed of Devonian limestone, slate, and grit, which appear to be the fundamental rocks of this part of Syria The plateau of Kawar, which intervenes between the Giaur Dagh and the Kurdish ranges, is formed of gabbro, nonte, schillerfels, and serpentine, of an age intervening between the Upper Chalk and the Eocene The Miocene strata which occupy so extensive a part of Northern Syria were formed, according to the author, under the waters of an arm of the Mediterranean, which extended inwards at the base of DI el-Koseir beyond the Kuweik and the vicinity of Aleppo, bounded by irregular ranges of emergent hills of Eocene and Cretaceous strata The formation consists of basal conglomerates of flint pebbles, passing into calcareous sands, clays, and finally the massive limestone (Grobkalk) already referred to, and has yielded forms of Operculina, Clypeaster, &c., clearly indicating its marine origin. This epoch was remarkable

To Mem on the Physical Geology and Geography of Arabia Petrea, Palestine, &c " (Pales in, Ixiloration Fund), 1885, pp. 103 12

for the display of volcanic energy on a vast scale Great sheets of august lava together with fuff and agglomerate. were erupted during the Miocene epoch, not only in Northern Syria but in the East Jordanic region to the south, and were again renewed in Post-Phocene times It is probable that to volcanic action we must refer the origin of some of the peculiar little lakes of Northern Syria, such as those of Homs and Kara, one occupying the bed of the Orontes, the other that of the Kara, where the ground probably fell in and became filled with water. The Phocene period is represented by both marine and freshwater strata, deposited in bays and depressions along the margins of uprising lands, formed of all the older formations, including those of the Miocene period All of these had been disturbed, upraised, and partially eroded before the deposition of the Phocene strata. In this, as in other physical phenomena of Northern Syria, we are reminded of those of Palestine and Egypt. Throughout all this region the Nummulitic and Cretaceous strata were disturbed and upraised into dry land, and subjected to extensive denudation at the close of the Eocene and again at the close of the Miocene epochs, so that the stratigraphical continuity of these Tertiary formations has been repeatedly broken.

100

It may be worth while, in conclusion, to glance at the points of analogy, as well as of difference, between the physical conditions of Syria and of the region to the south of the Lebanon In Northern Syria, and along the ranges of the Taurus and Anti-Taurus, the fundamental rocks on which are superimposed the great calcareous formations of Cretaceous and Tertiary ages consist of Devonian schists, greywacke, and limestone,1 together with masses of various igneous rock In Southern Palestine and the Sinaitic peninsula, on the other hand, the fundamental rocks consist of granite, gness, various crystalline schists of Archæan age, traversed by innumerable dykes of hornblendic, augitic, and felspathic rock, surmounted at intervals by Lower Carboniferous beds; this is a remark able contrast But a still greater, perhaps, is to be found at the next stage. All along the eastern border of the lordan Valley, south of the Sea of Galilee, extending southwards along the table-land of Moab, Edom, and the Arabah Valley, as well as through the Smaitic peninsula, and into Upper Egypt, the base of the Cretaceous series is represented by the Nubian sandstone, a formation of great persistency, and interesting from an architectural point of view for its extensive use as a building-stone in the great structures of Ancient Egypt; as, for example, in the colossal figures of Amenophis in the plain of Thebes, as also in the temples and sepulchres of Petra. This formation appears to be altogether wanting north of the Lebanon, where, according to Herr Blanckenhorn, the Cretaceous strata of the Turonian stage are the lowest of the series.3 The points of contrast, however, here terminate; for over the whole region from Upper Egypt and the Libyan Desert on the south to the Taurus Mountains on the north, a distance of 1000 miles and beyond, the Cretaceous and Eocene limestones were deposited, and formed part of the floor of the ancient ocean, the original limits of which it is hard to determine with any approach to accuracy.

NO. 1127, VOL. 44

At the close of the Eocene epoch this ocean bed was subjected to powerful movements. Large tracts, including the Libyan Desert and Egypt, Palestine and Syria, were elevated into dry land; while the strata were bent, folded, and faulted along lines ranging generally from north to south To this period is to be referred the production of the great Jordan-Arabah fault, which has now been traced at intervals from the Gulf of Akabah to the valley of the Orontes, a distance of over 350 miles, while the main features, especially the mountains, had the outlines which they now present marked out During the Miocene period, along with a partial re-submergence, volcanic action came into play over a region generally bounded by the Jordanic depression on the west, and extending from the Arabian Desert to the base of the Taurus, and the head waters of the Euphrates. In Northern Syria, extensive sheets of basaltic lava are found west of the Orontes Valley, as well as at Antioch, Aleppo, and other parts At a later period, bordering on the present, fresh erupuons were added. The region we have been considering has its natural boundary towards the north in the Taurus range, where a system of E-W flexures take the place of those of the region to the south, where (as we have seen) the prevalent direction of the flexures is EDWARD HULI meridional.

EUROPEAN BOTANY

Planta Europeæ enumeratio systematica et synonymica plantarum phanorogamicarum in Europa sponte esscentum vel mere inquitinarum Autore K Richter Tomus 1, pp 378 (Leipzig Verlag von Wilhelm Engelmann, 1890)

A / HAT is most wanted in systematic botany at the present time is a general flora of Europe, worked out for the different countries on one uniform plan, with the sub-species and varieties placed in their proper sub ordination under the primary specific types, and the synonyms worked out carefully The number of plants in Europe is about the same as in the United States For these Asa Gray planned a general flora in three volumes, of which the middle one, containing the Gamopetalæ, was published shortly before his death, and the first and third left in a forward state of preparation, Many years ago Mr Bentham planned and carried out, with the assistance of Baron von Mueller, a complete flora of Australia. There are 40 or 50 per cent. more plants in India than in Europe Sir Joseph Hooker's "Flora of British India," containing descriptions and full synonymy of every species, has reached the end of the Dicotyledons, and in the last part the Orchideæ are finished, so that five-sixths of the work is now done. There is, however, no such book in existence as a general descriptive flora of Europe. For Europe the difficulty hes far more in the bibliography than in the plants themselves An enormous number of subordinate forms have been described under specific names, and the number of channels of publication in the way of journals and reports of societies becomes greater and greater every year. Nyman's "Sylloge," published in 1854-55, and his later "Conspectus," have been a great boon to all European workers. Though they do not contain any descriptions, they give a tabular view of the whole European flora,

<sup>As determined by Hamilton Warington Smyth, Tchihatcheff, and others
Probably of Neccoman age
Representing thuse of the chalk-marl of England</sup>

tracing out in detail the geographical distribution of the species; and in the "Conspectors" especially, great pains species; and in the "Conspectors" especially, great pains has been taken to separate the subordinate from the has been taken to separate the subordinate from the not contain any descriptions. It deals with the geometric part of the special pains of the species much more briefly, indicating it within the compass of a single line. Its strong point is bibliography, and it gives under species a list of all the names that have been applied to it by the different authors, with a citation of the book and page great where each name is published, with a note of the date of one of the date of the property of the different authors are the substituted where each name is published, with a note of the date of the page of the property of the page of the page

Cultum.

Of course it is impossible for an author covering such a wide field to work out for himself all the details, and in the critical genera, such as Potamogeton, Festuca, Crocus, Iris, Tulina, and Narcissus, no two authors are ever likely to agree as to which should be classed as primary, which as subordinate types, and which as mere synonyms. The present portion of the work includes only the Gymnosperms and Monocotyledons. The author admits 250 European genera, 1830 species, and 840 sub species. He keeps up the oldest specific name published under any genus, not, as is usual in England, the name first published under the genus in which the plant is now placed. I find that a considerable number of books and papers published in England have not been taken into account . for instance, Maw's magnificent monograph of the genus Crocus, C. B. Clarke's monograph of the European species of Eleocharis in the Journal of Botany, 1887, p 267, and Arthur Bennett's work on Potamogeton, as summarized in the last edition of Hooker's "Student's Flora" The book has cost great care and pains, and will be found very useful by all who work at European botany I G BAKER.

OUR BOOK SHELF

The Missouri Botanical Garden 8vo, with several Maps and Engravings (Printed for private circulation by the Managers, 1891.)

111. Missouri Botanical Carden is situated at the city of \$1 Louis, and was founded by the late Henry Shaw. He was born at Sheffield in the year 1800, and emigrated to Canada, with his father at the age of eighteen, and a small isolated French trading post. He established himself in business as a dealer in cultery, made a fortune of 25,000 dollars by the time he was forty years of age, and then retuced from business. In 1840 he visited tourin the Old World. In 1851 he wisted Chatsworth, and particularly admired the garden and conservatories. This led him to entertain the idea of forming a large garden at home. One of the best American betasists, Dr self-with the control of the control of the control of the lost American botanists, Dr self-with the control of the control of the control of the lost and conservations. Dr belp and advice. In 1857 he opened a correspondence with \$ir William Hooker. He engaged from the Royal Botanic Carden in Regent's Park Mr. James Gurney to superintend the Carrying out of his plans. He ded in structed partly within and partly outside the limits of the toy of \$i\$. Louis, to be keep up as a Botanic Carden open

to the public, containing a museum and library.

On the recommendation of Dr Asa Gray, Mr. William
Trelease, who was then Professor of Botany in the Wisconsin University at Madison, was appointed in 1885
Director of the Garden, a post which he still holds, and
porosision was made for the establishment of a school
or strength of the work of the public of the control of the cont

The present volume contains a biographical sketch of the founder of the Gardens, a copy of his will, of the Act that was passed to enable him to convey the land to the trustees, because the control of the Control of

preached in Christ Church Cathedral on May 18, 1890, by the Bishop of Missouri. The book is illustrated by plans of the garden, a large number of views of the museums and other buildings, including Mr Shaw's house and a fine statue of Humboldt.

Everything is now in fall working order, and we have just received from Prof Trelease a capital synopsis of the American species of the difficult genus Epilobium, containing full botanical descriptions and figures of all the species. The herbarium now contains about 20,000 mounted sheets of howering plants and ferns, also a large collection of Fungi and other Cryptogamas.

Géologie Principes-Explication de l'Époque Quaternaire sans Hypothèses. Par H. Hermite. Pp 145. (Neuchatel. 1801)

On taking up this little book the geological reader is at once struck by the words "sans Hypotheses" in the title A volume on Pleistocene geology free from hypotheses would seem to him to usher in a new era in geology, and would be most heartily welcomed by him. The title of the present work, however, is insleading, the book is almost entirely devoted to theoretical explanations of purely hypothetical facts We have not space to notice in detail the various subjects of which the author treats. but as an example of his method we may point to his
"Origine des Pluies Quaternaires" (p 30) In this
section he accepts the hypothetical Quaternary "Pluvial Period "-which, by the way, seems to have been characterized by a singularly poor aquatic fauna and flora—and he then accounts for the supposed excessive rainfall during Tertiary and Quaternary time by the amount of vapour thrown out by volcanoes, adding that the small rainfall of the Secondary periods is accounted for by the absence of volcanic action during those periods! Then we meet with our old acquaintance the former excess of carbonic acid in the air and its influence on the ancient climate of the polar regions—possibly correct, but certainly hypothetical Further on, speaking of the origin of the continental platform at a depth of 200 metres, the author states that this feature results from the raising of the general level of the sea from the melting of the Quaternary ice, and from this hypothetical raising he arrives at the result that the mass of the Quaternary ice corresponded to the total mass of the sea now lying above the level of the continental platform Another speculation relates to the breaking through of the Indian Ocean across Siberia to the Polar seas, thus causing a milder climate, and accounting also for the parallel roads of Glen Roy and the terraces in Norway and Greenland We cannot pretend to follow the reasoning, but it is all somehow connected with the author's theory "qu'à une diminution de la densité des iners correspond un abaissement de leur surface "

Webster's International Puttomary of the English Language Revised and Enlarged under the Supervision of Noah Porter, D.D., L.L.D. (London George Bell and Sons, Springfield, Mass. U.S.A. G and C Merriam and Co.)

WERSTER's Dictionary is so well known on both sides of the Atlantic that it is unnecessary to do much more than note the appearance of the present edition. The work was published originally in 1828, after which it was steadily improved in successive issues. It has now been revised to horoughly, and with the aid of so many competent scholars, that for popular use it can hardly fail to present the control of the present of the properties of the present of the field in the preface to the English edition it is stated that no pains have been spared to make this part of the book "as prefice as possible in both text and illustration." The

definitions in particular branches of science have been revised by much men as Prof. H. A. Newton and Prof. E. S. Dana—names which are a sufficient guarantee for ke way in which the task has been accomplished. In the department of etymology, Prof. E. S. Sheldon, of Harvard University, has carefully dealt with the results presented in the last edution, bringing them into accord with the philological decase of the present day. The pictorial illustrations are numerous, and well adapted to the purposes for which they are inserted.

Elementary Chemistry, for Beginners By W. Jerome Harrison, F.G.S (London Blackie and Son, 1890)

THE volume of 144 yeages constat of an expansion of the author's notes of lessions prepared for teaching children from nine to thirteen years of age according to the outlines given in the education code. The information is conveyed in familiar language, and each chapter closes with a series of questions which har well reached the contract of the co

Examination of Water for Samtary and Technical Purposes By Henry Lellmann, M D, Ph D, and William Heam, M A Second Edition (London Kegan Paul, Trench, Frubner and Co, Ltd., 1891)

This fact that a second edition has been called for only two years after the issue of the first, shows that this excellent hand book has been very generally appreciated the authors have revised the work and made many additions to it chiefly of processes that have recently grown importance. Among the principle of the property of the first edition are now expanded into a chapter of threten pages entitled, "Biological Examinations" A table of culture phenomena of some of the more important microbes is given. But concerning this matter the authors state that "until pathogenic microbes are more interest than the control of the state of the concerning the state that it is not problem of the determination of the sanitary and technical value of water supplies"

The University of London

I no not with 10 entruse in the least Prof. Lunkester, whalshe sattement in your last inner, with which I entirely sprese, but I desue to point out that unless some energetic scion is taken very soon we are likely to be faither than very from the ideal which be has in view—namely, the establishment of a strong prefessional University in Condo. The only scheme at present in the field is that put forward by the Councils of University and King's Colleges in the proposed others for an Albert University.

This scheme has never met with the cordial support of a large section at least of the teaching staff of University College, and for section at least of the teaching staff of University College, and for the very obvoors reason that to des not constitute a professorial University, but creates a new examining body on which the two Colleges will be, in the heigining at any rate, largely represented The Albert University Charter would create a second Victoria University in Loudous Colleges will be, the Colleges will be, and the colleges of the University in Loudous was to facted. Illuviersity the Victoria in Loudou, but they seem to forget that this petitiogram excuse for a University—a scheme drinked by burseucentz rather than academic minds—sinth colly scheme in the field, and that, further, the Lord Presented of the Council has determined to hear by counsel, on an early day in June, what can be said for and against this scheme. It is further removed that the bear removed against this scheme It is lutther rumoured that the Burlington House Senate intends, after its recent discomfiture, to remain absolutely neutral. The danger, then, that we shall have a repetition in London of the difficulties of Manchester is a very repetition in London of the difficulties of Manchester is a very immediate one. Let no pront our exactly the anomalies of the Albert scheme. In the way independent of the Albert scheme. In the way independent of the Albert scheme in the property of the Albert scheme in the property of the Albert scheme in the Albert scheme So long as there is competition between the Colleges, so long as So long as there is competition between the Colleges, so long as they possess a double staff competing at every turn with each other for students' fees, this is unlikely to be remedied. Prof. Lankester speaks of a union of King's and University, and talks about their combined resources. The fusion of these two talks about their combined resources. The fusion of these two Colleges would certainly be the first stage to a true professorial University in London, but there is nothing in the Albert charter to bring this about it unites the two College, not for teaching but for examining purposes. But what is still worse, while these two Colleges will remain autonomous, the Albert charter proposes to admit any further autonomous bodies, the teaching of which can be shown to have reached a certain academic standard hese bodies will not be absorbed, but their independent staffs will be represented on the Faculties and Senate. Here we have will be represented on the Faculties and Senate. Here we have in fact the University of London over signin,—at first composed almost entirely of the two Colleges, afterwards, embracing all sorts and conditions of institutions in I ondon, and ultimately open to every isolated text book reader in the universe. It open to every solded text book reader in the universe. It cannot be therefore too strongly insisted upon that the Albert charter, if granted, will not call into existence a professional University, but federate a group, and an ever-wedning group, of competing institutions for the purposes of commentation. If it shed for a time any additional liaster on the technique staffs of the two Colleges—which I am much inclined to doubt—it will not achieve, what most of us have at heart, the establishment not achieve, what most of us have at heart, the establishment in Loudon, at any rate in the germ, of a great Unwersity in the Southsh or German sense. A University, on the scale we hope of the Royal College of Steines, and of the Cortal Institute without the least difficulty. With the death or transference of exiting teachers, whose premistry unterests would have of course of the contract of the which will only impede its ultimate realization, ought to meet with strenuous opposition from those who believe that a great professorial University must sooner or later be established in

The difficulty as to the granting of medical degrees will for long be the stumbling block of any scheme, but the true way to long be the stumbing block of any senteme, but the true way to surmount it seems to be that suggested by Prof Lankester—namely, the complete divorce of the climical teaching at University and King's Colleges from the selence teaching, and the establishment of separate chincal schools at the existing College bospatials. ment of separate chincal schools at the existing College bospassas on precisely the same footing with regard to the University as the other medical schools. The preliminary science teaching at the various medical schools might then be safely intrusted to University readers, who might continue to be, as they now largely

"Riementary teaching in many branches might for local convenience be still carried on at several centres.

NO. 1127, VOL. 44

are, penpatetic. These readers would naturally belong to the science faculty of the new University, and if largely paid by students' fees might be trusted to safeguard the "prehiumary scientific interests" of the medical schools. It seems to me, therefore, that some vigorous effort ought to be made to obtain the modification of the Albert University scheme in the sense indicated by the following proposals -

PROPOSALS IN TO TEACHING UNIVERSITY

No scheme for the constitution of a teaching University in

London will be satisfactory which does not I Place the appointment of the teaching staff, as well as the control of laboratories, libraries, and buildings, in the hands of a single executive body, hereinafter spoken of as the new University Senate, or of bodies, such as Faculties or boards

University Senate, or of bodies, such as Faculities or bards of study, to which it may delegate its powers

2. Confer on the new University Senate the power of graning degrees in all Faculities, including that of Medicine

3. Give to the teaching staff an immediate representation of one-third, and an ultimate representation of at least one-half, on

the new University Senate

the new University Schate
These conditions would probably be best fulfilled by
4. The immediate fusion of the Councils of University and
King's Colleges, and the Council or Governing Body of any
other institution doing work of admittedly academic character. in London, which may be willing that its laboratories and University Senate.

University Senate,
[This would remove any ground from the objection that the
two Colleges are claiming powers which they are not willing to
share with the Royal College of Science or the Central Institute
It provides for these latter coming into the scheme on the same

The granting of a Charter to a body consisting of these combined Councils together with representatives of the teachers in the combined institutions

The constitution of the new University Senate in the following manner -

A Immediate constitution-

(1) The fused Councils of King's and University Colleges or their representatives thurd of the total number

(2) The Councils of other academic bodies in London willing to be absorbed, or then representatives (3) Representatives of the teachers to the extent of one-

B. Illumate constitution-

(1) University professors, either as 1/50 facto members

arreasing processors, either as 1950 leave members or as representatives of the body of professors
 (2) Representatives of the Faculties (i e of the readers and professors of each Faculty)
 (3) Co-optitude members, not to be selected from the

teaching staff And possibly,

(4) Representatives of bodies willing to endow professorships in the new University, or to hand over to ships in the new University, or to hand over to the control of the University existing professor ships or lecture-hips, $\epsilon_{\mathcal{S}}$ (a) the Corporation of the City and the Mercers Companya trustees of Sir Thomas Gresham's estate, (b) the Ilaus of Court—provided these bodies are willing to attach the Gresham Lecturers and the Reader ships instituted by the Council of Legal Pducation ships instituted by the Council of Legal Pducation

ships instituted by the Council of Logar Physicians to the new University

(5) Representatives of the Medical Schools and Royal Colleges of Physicians and Sirgeons other than those selected by the Medical Faculty. This would only be a matter for consideration when the power to grant medical degrees became actual

7 The transition from the immediate to the ultimate con-stitution of the new University Senate in the following menner -

(a) By not filling up vacancies among the members contri-buted to the new Senate by the existing Coll ge Councils as such occur

(b) By the increase of professorial members and representa-tives of the Faculties.

8. The suspension of the power to grant medical degrees until such time as the Senste of the new University shall have satisfied the Lord President of the Council that an agreement has been reached with the Royal Colleges and the chief Loudon Medical Schools as to the terms on which medical degrees shall be granted

of granted 9 Providing, on the repeal of the Acts of Incorporation of University and King's Colleges which would accompany the granting of the new Charter, special regulations for the control of certain portions of the endowments or of certain branches of

of certain portions of the endowments of of certain branches of the College technic, which it may not seem possible or advisable at present to hand over without special conditions to the manage-ter of the control of the control of the control of the control portion); at King College 10. Paying due regard to the pecuniary interests of examing techner (many of whom depend entirely upon students fees) in the appointment of future University professor or readers. In might be willing to surrender the title of College professor, that of University reader, but not creating the occupants of charm in any of the existing Colleges in the feet professor, that new University.

In this meresketch I have said nothing as to how faculties and boards of study much the constituted or as to how the University should grant degrees, for these seem to me "academic "prob-lems, a problema to bethrashed out by the University is elliwhen it is once moroprosited "Objection will be taken to much of the above by many individuals, but I believe it forestandows the the above by many individuals, but I Delieve it ioresnatures the direction in which the only wheme at present under discussion must be modified if it is to lead to the ultimate extablishment of a great teaching. University in London, and not to a mere organization of teachers for examination purposes. KARL PhARSON,

It seems to me that the force of the approxime of Ponds Landener and Romany in low seeds. Nat USE (May 8), pp. 76, 78), to far as they harmonize with each other, would have to be deatited, if the man object of a University were to foster that premiture specialism, which, under the acholiship system, has recommended and the seeds of the control of th of the great scientific societies makes one only too familiar. The example of this has been well set by at least one of the great metropolitan day schools — The fatal weakness of the arguments referred to is that they spnore, as no University ought to do, the claims of general education. If the advancement of sclentific research is really desired by University and King's colleges, all they have to do is to institute on their own account a diploma of the nature of the Associateship of the Royal School of Mines or College of Science, and make the training for it so or names or college or Science, and make the training for its ogod and thorough that the pussessors of such a diploma shall be such a diedectation in those "commercial" quarters to which Prof. Ramssay appeals as a over of final sulfurinty, that they shall drive such creatures as 18.5c 's out of the field. Special brampower, highly developed, it no doubt a splended thing in its power, mighty developed, is no doubt a precided thing in way, and recognition of it in the field of science is fully provided for in the B Sc. honours, and in the ultimate D Sc degree, but, in considering the terms on which a degree should be given, general education and culture cannot be left out of account. In ermany something of the sort is guaranteed by the examinatio which have to be passed on leaving the gymnasium (or high school) before students proceed to the University to specialize; in England it has been found necessary to institute the matriculain augustion it has been sound necessary of markets the matricular tool examination. That need, however, is no longer so imperative as it was, and for my own part 1 see no real objection to the "leaving certificate" of the Oxford and Cambridge Exthe "leaving cerificate" of the Usford and Cambridge Ex-amining Board being accepted in lien thereof, for I spak of what I know, when I say that this entries with it a guarantee of so much education and culture as the Marticulation Examination does, and often a great deal more. I would only supulate that a should include one modern language and one branch of

scence Prof. Ramsay has over-ridden his horse, by the emphatic preference he gives to a German degree. He is a comparatively young man, but some of us (who are not yet quite senie), can remember the time when the facilities for obtaining the German Ph.D degree were such (they are such to this day in America), that the degree became a by-word and a represseh, and still

NO. 1127, VOL. 44]

carries with it suspsesses altogether disadvantageous to those who have taken the genuine degree in Germany. This is nirely who have taken the genuine degree in Germany. This is not construct that the second of the second of the degree of the degree of the degree of the degree of M.A., which in the eyes of the vulgur is upposed to represent higher melletuchal attainments that the M.A., which is the degree of M.A. which is the eyes of the vulgur is supposed to represent higher melletuchal attainments that the M.A., can we expect greater virtue in a small and brand new Univer-sity struggling to "make both ends meet"? Were any further illustration required of the way things would be likely to drift Were any further with small and independent degree granting corporations, we might find it in the readiness with which the authorities of King's College threw over Latin two years ago in the mercantile deconcept hrew over Latin two years ago in the mercantile de-partment of their school (then in a state of depression), at the mere bidding of the Chambers of Commerce, although its retunion had been advocated by two leading scientific men. The really inspiring motive of this agitation is, I tblink, issuitely kep in the background

Wellington College, Berks, June 1

ONE of the taunts most frequently levelled at the London University—or "Burlington Gardeas," to use Prof. Lankseite", favourie expression—by certain professor of University Cellege for a first contract the contract of the University that this should not be done been privously told that there was a "text understanding" at the foundation of the University that this should not be done But I'red, Ray Lankester goes far beyond the assection of a foundation of the property of the same of the private of the same of the sa gether to see, for it was the expressed intention of the founders of the University that its powers and privileges should be the same as those of the Universities of Oxford and Cambridge. Testimony as to this pledge may be found in the evidence given before the recent Commission. The late Dr Carpenter's view of this matter was stated by Mr Dickins in his communication of this matter was stated by Bar Lickins in his Communication to NATURE. Convectation has, years ago, voted in favour of the establishment of University Professorships and Lecture-ships, though I of not in the least believe that the graduates would sanction any proposal involving that the University should prepare candidates for its examinations, or compite with the ordinary work of the Professors in University College and other simular instatutions. Whether research is or in not carried. on successfully at University College is a matter on which I express no opinion. But, however this may be, it should be remembered that the students of this College have become only a small fraction of the candidates for London degrees. It would a small fraction of the candidates for London degrees. It would be, it seems to me, in the public interest that the University should make provision for the encouragement and reward of content for the cancellar for the content for the carecta and a power to extend the boundaries of knowledge. That the University has only one solitary Professor and e.g. believe, in great measure to the narrowmanded and university professor of University College, and to the fear lest some andown in also did chance to be diverted to the University.

processory of contents of contents of the test of the

College students being compolled to meet elsewhere instead of in the College on account of there being something of a religious character connected with their meetings, while there are facts of a different character in the battory of King's College which may be easily remembered. That a feferial University constanting of institutions so dissuming would work harmonously? I very much care but little, except on ourseaff and the care but little, except on ourseaff and before the care to be little, except on ourseaff and before when the care of doubt. Probably the graduates of the existing University would care but little, except on general pablic grounds, about Uni-versity and King's Colleges having power to grant degrees, if as taken for that of the University of London. A syet the Victoria University is not a conspicuous success, and the I ondon Uni-versity examinations are still held at Owen College

versity examinations are still held at Owens College With the views set forth by Mr. Thiselion Dyer I should be disposed in great measure to agree, though there are some points on which I should have liked to make some remarks, but I fear, if I did so, I should trespass too far on your space. London, May 29

THOMAS TYLER. London, May 29

THOSE who have taken part in the interesting discussion on the University of London, in your columns, have all viewed the subject from the academic standpoint. Would it not be well to consider it also from another point of view, viz that of the educational needs of London? Frof Ramsy contends bounds of Knowledge. It is usurly more accurate to say that it University, under the conditions that now easily, has two main functions—the one the extension of the bounds of knowledge. by research, and the other the wide diffusion of that knowledge by research, and the other the wide diffusion of that knowledge. The purpose of such diffusion should be to afford, as far as possible, to every individual the opportunity of obtaining such a training as would qualify him or her to take part in the development of sonic branch of knowledge, or at any rate to follow with appreciation and interest the advance made by others

It needs no argument to show that it would be for the advantage of research, and for the well-being of the community, that real University training should be as widespread as possible Ability and bent for some special study may frequently not be developed until somewhat late in life, after a husiness career has been begun. There is scarcely a branch of science that does has been begun Inere is careely a branch of science coardoors not owe much to investigators whose researches were carried on during bours spared from some bread-winning occupation. The late Prof. John Morris was in early life a chemist in the Borough, Dr. James Croll was for years the janitor of the Borough, Dr. James Croll was for years the janior or the Andersonian University, Glagow, even in the very number of NATURE containing Mr. Dyer's letter, the cass of M. Rouauli, one of the poincers in the geology of Britanay, is mentioned, who did his early work while carrying on the business of hardenser. A University training would have been of inestimable value to such students as these (and there are hundreds of such. with capacity for good work, scattered over London and the country), but no provision is made for them in our existing

Surely the important question therefore is, What kind of University would discharge most effectively for London the duty of providing for the needs of every class of students? Fhe University should clearly recognize all organized teaching of University should be supported to the control of the c verity hould clearly recognize all organized teaching of University rank, whether given within the walls of a specified College or not. One of the most urgent neerly of London is a coordinating head for all its multinons higher effectational species. The only University that will really adequately meet verified to the control of the c

The new teaching University for London should have as its The new teaching University for London should have as its accredited professor and lectures the staffs of University and King's Colleges, the Koyal College of Science, the various medical schools, and any other inclutions of equal mak, and in metropoles at convenient central. It would be the property of the extension of the principle admitted into the drift scheme for the reconstitution of the University of London, via. that of requiring from every University teacher a syllabus of his course of teaching, and further, by making such syllabus the beast of the semiliation, to incorporate all the work done by the accredited

teachers of the University into its curriculum for degrees. This would make it nosmble to one the university career to would make it nosmble to be under the control of the university career to come of study in three or four years, evening students would take nine or ten, and the curriculum could without serious difficulty be modified to meet the conditions.

R D. ROBERTS

I WOULD ask whether it is quite fair to assume that, because Convocation has rejected the Charter proposed for the Uni-versity of London, it therefore follows that that body is out of sympathy with the attempts that are being made to establish a "real University," whatever that may mean Is it not possible that a large proportion of those adverse votes were recorded because there were elements in the scheme which were felt to be impracticable or open to serious objection? At all events, I feel sure that there are many who would refrain from regarding the vote as being an expression on the main issue.

the vote as being an expression on the innin issue.

The views so well put forward by Frof Ray Lankester as to
the undesirability of establishing what he terms federal Unversities fally enlist our sympathies, but are we not saling very
near the wind in the suggestion that University and King's
Colleges and "other institutions" should be incorporated on University lines?

I say, by all means avoid centralization and beware of the "never-ending Committees and schedules of such clumsily-organized Universities" But what of value is then left that University College does not already possess? Would the appropriate definition and allotwent of degrees of all shades and appropriate definition and another of the work and influence of Graham, Sanderson, Sharpey, Foster, Williamson, and Prof I ankester himself, or have added to the benefit they have conferred upon University College? One does not surely regard the granting of degrees as an important element in the German the granting of degrees as an important element in the German University: 1st distinguished professors are ont Berlin men or Straschurg men—they are pupils of Liebig, of Wohler, of Bansen, and the like, and its students are not regarded as graduates of Herdelberg or Giessen, but in like manner as pupils of so and so And University (Ollege 1s, I lake it, insuch more nearly in function a German University now than ever it is likely to be as a fideral University. I verily believe that such is the taste of the so called properly ordered English mind for is the taste of the so called properly ordered English mind for schemes, plans, and organizations, that a governing body, even though largely composed of the most uncrystallizable elements, would shortly he found carefully hedging itself round (and the students) with that beautiful machinery which Prof. Lankester so heartily detests Prof Ramsay's association of "examina tion on the brain" with the London University undergraduate I fear does the said undergraduate an injustice, if it is meant to differentiate him from his fellows of the "real Universities"

differentiate him from his fellows of the "real Universities". The men who regard the College Calendar with its traditional quistions as their web. means, and whose only other study is the disopercasses of the examiner, are shouldess, and their name is legion. If I could think they were confined to the "Barlington Gardens University", I, for one, would vote against the alteration of one jot or stitle of the present organization, if only lest they might be disturbed from their resting place there May 30.

Quaternions and the Ausdehnungslehre

Quaterniona and the Ausdehnungslehre Proor Ginis's second long letter was ordently written before he could have read my reply to the first. This is infortunite, in the question now raised. Of course that question is naturally confined to the invention of methods, for it would be preposterous to compare Gramman with Insuffice as an analyst confined to the invention of methods, for it would be the English, and have consulted once more the authorities there from the end of the method withing which I should have liked to after. There is much, of course, which I should have liked to after There is much, of course, which I should have liked to after There is much, of course, which I should have liked to after the course of the the Ausdehmungilehrs been asked of me, I should certainly have declined to undertake it. Since 1860, when I ceased to be a Professor of Mathematics, I have paid no special attention to general systems of Sets, Matrices, or Algebras, and without much further knowledge I should not attempt to write in any detail about such subjects. I may, however, call attention to the facts which follow, for they appear to be decisive of the question now raised Cauchy (Comptes Rendus, 10/1/53) claimed quaternia as a special case of his "clefs algebriques." Grassmann, in turn, (Compter Rendut, 17/4/54; and Crelle, 49) declared Cauchy's methods to be precisely those of the Ausdehndeclared Cauchy's methods to be precisely those of the Austehnungslehre But Hamilton (Lecturer, Pref. p (64), foot note) says of the clefs algebriques (and therefore, on Grassmanns' come showing, of the methods of the Austehnungslehre) that they are "incitated in that theory of Siris in algebra.

appounced by the in 1835... of which SETS I have always considered the QUAIRRNIONS... to be merely a farticular CASE."

a fartreuter CAE." On the Description regarded and little has no five for the control of the con But all this has nothing to do with Quatermons, regarded as liere, as anyone interested in the matter can readily consult the

In regard to Matrices, I do not think I have ever claimed anything for Hamilton beyond the «parable », and the symbolic cubic (or biquadratic, as the case may be) with its linear factors, and these I still assert to be exclusively his. My own work in this direction has been confined to Hamilton's ϕ , with its square-

The Spinning Ring

I CANNOI suppose that the mathematicians are all in error, but venture modestly to ask what are the assumed conditions under which a girdle round the earth at the equator would be subject to strain. If the surface of our globe at the equator were continuous and level land, about 30,000,000 of persons more than 1000 to a mile-standing at equal distances and joining hands, would form a girdle without any strain, or the girdle might be formed of separate pieces of wire placed end to end in close contact, which, if afterwards soldered, would form a girdle, without strain

without strain and the strain of the strain

4 Serieants' Inn. Fleet Street, April 30

BISHOP COURTENAY'S questions may perhaps be clearly answered as follows The centrifugal force of a free spinning answered as joilows I not Centinugal sorte of a tree spinning hoop has to be balanced by its perspheral tension; but this having a large tangential and a small radal component, acts at a datadvantage, and may have to be very big to balance over a moderate centrifugal force. The larger the boop the more marked lat the magnitude of the tangential component as compared with the radal or effective component; so that a hoop 8000 miller in dameter could not rotate even once a day without processing the component of the component of the component of the compared with the radal or effective component; so that a hoop 8000 miller in dameter could not rotate even once a day without processing the component of the componen tearing itself asunder.

NO. 1127, VOL. 44]

An actual girdle round the earth is not dependent on pert-pheral tension for balancing its centrifugal force, since it is subject to an overpowering centripetal force due to the earth's

The statement made by Mr. Herschel on p. 514, vol. zliii., involved not a 20-fold stress but a 20-fold speed, which means a 400-fold stress. OLIVER I. LODGE

The Use of Startling Colours and Noises.

Last January a friend showed me a smew (Mergus albellus) shot on the Dee, near Chester, the crop of which he had found to be full of young flat-fish. He called attention to the dazzling whiteness of the bird's breast, and suggested that it must frighten the fish, and so be a disadvantage to it A little consideration showed that the effect would be precisely the reverse. As long as the flat-fish remains at rest, its colouring assimilates so closely to the sand on which it lies, and with which it partly covers to the sand on which it lies, and with which it partly covers itself, that it would not be easily each by the sime. But if, startled by the white object flashing down on it from above, it moves, it is seen at once, and of course captured. Anybody who has ever collected small insects, such as beetles, will admit the truth of this at once

the truth of this at once The same effect is probably produced by the hooting or screaming of owly when hunting at night. A mouse, which would be invisible even to the sharp eyes of an owl when motionless, would be seen at once if startled into motion by the sudden "short" of the bird, whose noiseless flight had brought it unperceived into close proximity.

it unperceived into close proximity.

Perhaps these suggestions may serve to explain other apparent difficulties in the way of natural selection

The brown owl hoots throughout the winter here, so that it cannot be a sexual call

ON SOME POINTS IN THE EARLY HISTORY OF ASTRONOMY.

ıν

FROM what has been stated it is not too much to assume that the Egyptians observed the sun on the borison. This being so, the chances are that at first they would observe the stars on the horizon too, both stars probable by the very careful way in which early astronomers defined the various conditions under which a star can rise or set, always, be it well remembered, in relation to the sun. They spoke of a star as rising or setting

	on Rising.	Morning ,	True or cosmic	Sun rising.		
Star at eastern horizon			Apparent or heliacal.	Sun not yet risen, but depressed below horizon sufficiently to enable the star to be seen.		
	Actioning.	Evening	True or achronic	Sun setting		
				Sun just set, and depressed below horizon sufficiently to enable the star to be seen.		
	o. Setting	Evening	True or cosmic.	Sun setting.		
Sinr at western horizon.			True or cosmic. Apparent or hebacal	Sun set, and depressed below horizon sufficiently to enable the star to be seen		
that at western Horizon,			True or achronic	Sun rising.		
		Morning.	True or achronic Apparent or heliacal	Sun not yet risen, but depressed below horizon sufficiently to enable the star to be seen.		

It is Ideler's opinion that, in Ptolemy's time, in the case of stars of the first magnitude, for helical triangs and settings, if the star and sun were on the same horizon a depression of 1". Was taken, if on opposite horizons a depression of 7". For stars of the second magnitude, these values were 1,4" and 8\$." But it temples the second that the support of 1". It is the support of 1" and 1"

Before we begin to consider the question of stars at all, we must be able to describe them to speak of them in a way that shall define exactly what star conting to its constellation on its equatorial or celiptic co-ordinates, but all these means of reference were unknown to the earthest observers; still we may assume that the Egyptians could define some of the stars in some fashion, and it is evident that we here approach a matter of the very highest importance for our subject.

So far, as we have been dealing with the sun and the observations of the sun at rising and setting, we have taken for granted that the amplitude of the sun at the estituced does not change: the amplitude of 5 at Thebes, so the state of the sun at the state of the sun at the state of the sun at the state of the state

In the last lecture we considered what were called the ecliptic and the equatorial co-ordinates. The ecliptic was the plane in which the earth moves round the sun, and 90° from that plane we had the pole of the heavens;

eclipite north and south up to the pole of the heaven, and celestal longitude we recknod along the plane of the eclipite from the first point of Anes. We had also declination recknode from the equation of the earth prolonged to the stars, and right ascension recknode along the equation from the first point of Aries. The pole of the heavens then we must regard as fixed, but the pole of the earth is not tracel, but slowly moves round it. In consequence of that movement there is a change of declination in a star's plate.

The cosmic rising meant that the star rose, and the

cosmic setting meant that the star set, at the same moment

as the sun—that is, that along the eastern horizon we should see the star rising at the moment of sunrise, or along the western horizon a star setting at the

moment of the sun setting. The achronical rising is different from the cosmic in this respect—that we have

the star rising when the sun is setting and setting when the sun is rising. Finally we have the heliacal

rising and setting, that is taken to be that the star

appeared in the morning a little in advance of the surrise, or set at twilight a little later than the sun. The

following table from Biot 1 should make matters quite

Going back to the tables, we find that the amplitude of a body rising or setting at Thebes or anywhere else depends upon its declination, so that if from any cause the declination of a star changes, its amplitude must change at any particular place

That is the first point where we meet with difficulty, because if the amplitude changes it is the same as saying that the place of star rising or star setting changes, that is, a star which rose in the east in a certain amplitude this year will change its amplitude at some future time. The real cause of the precession of the stars hes in

the fact that the earth is not a sphere, its equatoral diameter being longer than its polar diameter, so that there is a mass of matter round the equator in excess of what we should get if the earth were sphereal. Suppose what we should get if the earth were sphereal. Suppose differently presented to the sun, one part being nature than the other, the neater part being attracted more forcibly. If we take the point where there is the greatest attraction, and draw a line to the least, we can show that the case stands in this way: that the surs pail the case stands in this way: that the surs pail the sun and the point in a direction parallel to the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of the line joining the centre of the sun and the centre of

Continued from p. 60. NO. 1127, VOL. 44] ring, and another force at right angles to it. The question is, what will that force at right angles do?

Here we have a model showing the rotation of the

Here we have a model showing the rotation of the surf ton its ass, and the concurrent revolution of the sur round the earth once a year. To represent the surf round the earth saw, instead of retaining its direction to the same point as it did before, is now jesscribing a circle round the pole of the heavens. It is now a recognized principle that there is, so to speak, a wobble of theeathrd axis round the pole of the heavens in consequence of the axis round the pole of the heavens in consequence of the ring being greater than on the part of the equatorial ring being greater than on the part of the equatorial ring the properties of the part of the surface of t

by the moon, the moon being so very much nearer to us.
In consequence, then, of this lumbsolar precision we have a variation of the points of intersection of the planes of the earth's equator and of the ecliptic; in consequence of that we have a difference in the constellations in which he am is at the time of the solitores and at the equinoxes; and, will more important, we have another difference, in the constellation of the state.

change from century to century

108

Having thus become acquainted with the physical cause of that movement of the earth's axis which gives rise to what is called the precession of the equinoxes, we have next to inquire into some of the results of the movement. The change of direction of the axis in space has a cycle of something between 25,000 and 26,000 years
As it is a question of the change of the position of the
celestial equator, or rather of the pole of the celestial equator, amongst the stars in relation to the pole of the heavens, of course the declinations of stars will be changed to a very considerable extent, indeed, we easily see that the declination of a star can vary by twice the amount of the obliquity, or 47°, so that a star at one time may have zero declination—that is, it may lie on the equator—and at another it may have a declination of 47° N or 5 Or, again, a star may be the pole star at one particular time, and at another it will be distant from the pole no less than 47° Although we get this enormous change in one equatorial co-ordinate, there would from this cause alone be practically no change with regard to the corresponding co-ordinate—that is to say, the position of the star with reference to the earth's movement round the sun movement takes place quite independently of the direction of the axis, so that while we get this tremendous swirl in declination, the latitudes of the stars or their distance from the ecliptic north or south will scarcely change at all.

Among the most important results of these movements dependent upon precession we have the vanous changes in the pole star from period to period, due to the various positions occupied by the pole of the earth's equator. We be pole stars will change, for a pole star is merely the star near the pole of the equator for the time being. At present, as we all know, the pole star is in the constellar on Ursa Minor. During the last 15,000 years the pole from the pole of the equator of the time to the pole of the pole star is in the constellar which is equal to the obliquity of the ecliptic; so that about 10,000 or 12,000 years ago the pole star was no longer the little star in Ursa Minor that we all know, but the big star Vega in the consellation Lyra. Of course the star in Ursa Minor that we all know, but the big star Vega in the consellation Lyra. Of course the star in Ursa Minor that we all know, but the big star Vega in the consellation Lyra. Of course the star in Ursa Minor that we all those, but the last presence the pole star was practically the same as

Associated with this change of the pole star there is another matter of the highest importance to be considered, because as the axis is being drawn round in this way, the point of intersection of the two fundamental planes, the plane of the earth's rotation and the plane of the earth's

revolution, will be liable to change, and the period will be the same, about 25,000 years. Where these two planes cut each other we have the equanous, because the intersection of the planes defines for us the vernal and the section of the planes defines for us the vernal and the between these points we have the solitices. In a period of 25,000 years the star which is nearest to the equinox will return to it, and that which is nearest the solitice will return to it. During the period there will be a constant change of stars marking the equinoxes and the solitices.

Flune 4, 1891

can be a star marking the equinoses and the southers and the southers are some anong the spoints in the sun syearly path there so the same of the spoints in the sun syearly path the sun of the spoints of the sun of the s

Very fortunately we have such a means of calculation, and it has been employed very extensively at different periods, chiefly by M. Biot in France, and quite recently by German sarromeres, in calculating the positions of the stars from the present time to a period of 2000 years cacwary, the listude, longitude, right sacension, declination, and the relation of the stars to an equinox, a solitice, or a pole, as frank as 2000 years B.C. Since we have the planes of the equator and ecliptic cutting each other at different points in consequence of the cause which I should be such as 2000 years B.C. Since we have the planes of the equator and a variable equator different points. In consequence of the cause which I so not fixed, so that we have not only a variable equator the planes of the country of the planes of the cepture tiself is not fixed, so that we have not only a variable equator these calculations is to determine the has been done these calculations is to determine the relations and the results of these variations.

A simpler, though not so accurate a method, consists in the use of the precessional globe, ent of which I have here. In this we have two fixed points at the part of the precessional globe, one of which I have here. In this we have two fixed points at the part of the precession of t

If we wish to investigate the position of things, say soop years ago, we bring the globe back again to its bearings, and then adjust the screws into the holes. We will be the second of the second of the proper for the period. We will be the second of the proper for the period. We will be the second of the period of the period of the that time all we have to do is to paint a line on the globe in some water-colour, by holding a camel's harp pendid at the east or wear point. That line represents the equator Soop years ago. Having that line, of course the lineture of the period of the period of the period of the period culture of the period of the period of the period of the period of the second of the period versal equinox. Or if we take that part of the ecliptic which is nearest to the north pole and therefore the declination of which is greatest, uz. 23½ N. we have there the position of the sun at the summer solute, and 23½ S. will give us the position of the sun at the winter solutice. So by means of such a globe as this it is quite possible to determine the position of the equator among the stars, and note those four important points in the solar year, the two equinoxes and the two solstices. I have taken a period of 8000 years, but I might just as easily have taken a greater or a smaller number By means of this arrangement, therefore, we can determine within a very small degree of error without any laborious calculations, the distance of any body north or south of the equator, s.e. its declination

The positions thus found, say, for intervals of 1000 years, may be plotted on a curve, so that we can, with a considerable amount of accuracy, obtain the star's place for any year Thus the globe may be made to tell us that in the year 1000 AD the declination of Fomalhaut that in the year 1000 A.D the declination of Formalination was 35°S, in 1000 B.C it was 42°, in 2000 it was about 44°, in 4000 it was a little over 42° again, but in 6000 B.C to about 22°

The curve of Capella falls from 41°N at 0 A.D., to 10°

at 6000 BC., so we have in these 6000 years in the case of this star run through a large part of that variation to

which I drew your attention

Here is the curve of Sirius. This star, in o AD, had a declination of 24° S; but 5000 years BC it had a declination of something like 31½° In Sirius we have the curve plotted from the computations of Mr. Hind, who has kindly placed them at my disposal other computations supplied by him. I have ascertained that the globe is a very good guide indeed within something like 1" of declination, always assuming that the star has no great proper motion. Considering the difficulty of the determination of amplitudes in the case of buildings, it is clear that the globe may be utilized with advantage, at all events in the first instance.

Now that we are familiar with the effect of the precession of the equinoxes in changing the amplitudes of the rising and setting places of stars, we can return to the consideration of the temples So far, we have considered those built in relation to the sun, in the case of which body there is, of course, no precessional movement, so that a temple once oriented to the sun would remain so for a long time. After some thousands of years, however, the change in the obliquity of the ecliptic would produce a small change in the amplitude of a solstice

Suppose we take, as before, that region of the earth's surface in the Nile valley with a latitude of about 26' N The temples there built to observe the sun will have an east and west aspect true if they have anything to do with the sun at the equinoxes, and will have an amplitude of about 26° N. or S. if they have anything to

do with the sun at the solstices

The archæologists who have endeavoured to investigate the orientations of these buildings have found that they the orientations of these buildings have round that they practically face in all directions; the statement is that their arrangement is principally characterized by the want of it; they have been put down higheldy-puggledy, there has been a symmetrophobia, mitigated by a general desire that the temple should face the Nile. This wew desire that the temples should face the Nile. It his view may be the true one, if stars were not observed as well as the sun; for at Thebes, if any temple have an amplitude more than 26° N or S. of E. or W, it cannot by any possibility have been used, as we have seen the temples at Karnak might have been used, for observations of the sun; for since the maximum declination of the sun is almost 24½° (it is at present only 23½°), represented by an amplitude of 27°, no temple oriented in a direction more northerly or more southerly could get the light of the sun along its axis.

Let us see, then, if the builders of them had any idea in their minds consected with astronomy. If they had, we may conclude that there was some purpose of utility to be served, as the solar temples were used undoubtedly, among other thungs, for determining the exact length of the solar year. When we come to examine these non-solar temples, the first question is, Do they resemble in construction the solar ones? Are the horizontal telescope conditions retained? The evidence on this point is overwhelming. Take the temple of Denderal it points a baye enflated of it. In many others construct would in the conditions of the solar points of the sola to be served, as the solar temples were used undoubtedly have enfiladed it. In many others pointing well to the north or south, the axis extends from the exterior pylon to the Sanctuary or Naos which is found always at the closed end of the temple We have the same number of pylons, gradually getting narrower and narrower as we get to the Naos, and in some there is a gradual rise from the first exterior pylon to the part which represents the section of the Naos, so that a beam of horizontal light coming through the central door might enter it over the heads of the people flocking into the temple,

and pass uninterruptedly into the Sanctuary.

In these, as at Karnak, you see we have this collimating
axis We have the other end of the temple blocked, we have these various diaphragms or pylons, so that, practically, there is absolutely no question of principle of construction involved in this temple that was not involved

in the great solar temple at Karnak itself.

We made out that in the case of the temples devoted to sun-worship, and to the determination of the length of the year, there was very good reason why all these attempts should be made to cut off the light, by all these diaphragms and stone ceilings, because, among other things, one wanted to find the precise point occupied by the sunbeam on the two or three days near the winter and summer solstices in order to determine the exact inoment of the solstice

of the solutice
But if a temple is not intended to observe the sun,
why these diaphragms? Why keep the astronomer,
good reason indeed, because the truer the orientation
of the temple to the star, and the greater the darkness
he was kept in, the sooner would he catch the rising
star. In the first place, the diaphragms would indicate
the true line that he had to watch, he would not have to search for the star which he expected; and obviously the more he was kept in the dark the sooner could he see the

The next point that I have to make is that in the case of some of these temples which are not directed to the sun we get exactly the same amplitudes in different To show this clearly it will be convenient to bring together the chief temples near Karnak and those having the same amplitudes elsewhere We can do this by laying down along a circle the different

amplitudes to which these various temples point amplitudes to which linese various temples point 10 begin with, I will draw your attention to those temples which we have already discussed with an amplitude of 27 or 26, at Abydos, Thebes, and Karnak. Next we have non-solar amplitudes at Karnak and Thebes, associated with temples having the same amplitude at Denderah, with temptes having the same amplitude at Denderah, Abydos, and other places. We have-the majority of the non-solar temptes removed just as far as they can be in amplitude from the solar ones, for the reason that they are as nearly as possible at night angles to them. We have temples with the same amplitude. high north and high south, in different places—temples, therefore, which could not have been built with reference to the sun; just as we have at different places temples with the same amplitudes which could have been used for solar purposes.

In connection with the possible astronomical uses of these temples, I find that when one of these temples has been built, the horizon has always been very carefully left open; there has always been a possibility of vision along the collimating axis prolonged. Lines of sphinxes have been broken to ensure this; sit Medinet Abou, on the opposite side of the river to Karnak, we have outside this great temple a model of a Syrain fort. If we prolong the line of the temple from the middle of the National Conference of the Syrain fort. If we prolong the line of the temple from the middle of the National Conference of the Syrain fort. If we prolong the line of the Conference of the National Conference of

It may be said that that cannot be true of Karnak, because we see on the general plan that one of the temples, with an azimuth of 7; Nn, had its collimating axis blocked by numerous buildings. That is true; but when one comes to examine into the date of these buildings, its found that they are all very jate, whereas there is evidence that the temple was one of the first, if not the very first, of the temples built at libeds built at libeds.

Markette spent a long time in examining the temple of Karaak. His idea is that the part of the temple near the Sanctuary represents the first part of the building, and at that time the great temple of Karnak-enormous though it is now—was so small and entirely out of the existence might have been entirely neglected. There was first a square court like the court of the Tabernacle, and very shortly after that a very laboured system of pylons was introduced to restrict the light. The next stage shows the Sanctuary thrown lasted was from the Stage shows the Sanctuary thrown lasted was from the by the addition of pylons, until finally, after two or three extensions, the length of the temple was quadrupled So that the proof is positive that at first the horizon of the temple of Mast was left prefetcy clear. Why it was

subsequently blocked I shall suggest afterwards. The next point to be noticed is that there is in very many cases a rectangular arrangement, so that if the sun were observed in one temple and a star in the other, there would be a difference of 60° between the position of the sun and the position of the star at that moment. This sun and the position of the star at that moment. This that the star is t

If we look at Denderah we find that we have there a large temple inclosed in a square temenos wall, the sides of which are parallel to the sides of the temple, and also little temples a temple to the sides of the temple.

a little temple at right angles to the principal one.

It is hardly far to asy that a rectangular arrangement, repeated in different localities, is accidental, it is one which is used to some extent in our modern observatories.

The perpetual recurrence of these rectangular temples shows, I think, that in all the pairs of temples which are

thus represented, there was some definite view in the minds of those who built them.

Another point is that, when we get some temples pointing a certain number of degrees south of east, we get other temples pointing the same number of degrees south of east, we get other temples pointing the same number of degrees south of west, so that some temples may have been used to observe risings and others settings of stars in the same declination. It is then natural of course to conclude that these temples were arranged to observe the rising and setting of the same stars.

J. NORMAN LOCKYER.
(To be continued)

BOTANICAL ENTERPRISE IN THE WEST

WE have several times had occasion to mention the mission of Mr. D. Morris, the Assistant Director of the Royal Gardens, Kew, to the West Indies, in connection with the extension and organization of

botamical stations in the British colonies of that re-gion; and the Kew Bulletin for May and June, as we have already noted, contains his report thereon. It is a lengthy and interesting document, from which we propose to extract some particulars that may be welcome to our readers, and serve to put on record the reviving enterprise in the development of the natural resources of that part of the Empire. The primary object of Mr Morira's visit was to settle the practical details of a scheme for establishing and administering a number of smaller botanical gardens in connection with the larger gardens of Trinidad and Iamaica. The mainlarger gardens of Trinidad and Jamaica. purpose of these gardens is to raise plants of economic value, suitable for cultivation in the various islands, " and to do all that is possible to encourage a diversified system of cultural industries, and thus relieve the planters from the one or two staples to which they have hitherto confined their attention"; but they will also be made, as far as possible, pleasant places of public resoit Mr. Morris met with a hearty reception everywhere, and great interest was manifested in the work by the negro freeholders, in some of the islands, as well as the English colonists. The men in charge of these experimental stations, as they may be called, rather than botanical gardens, are they may be called, rather than bolanical gardens, are mostly trained men from Kew, and Kew is the centre from which plants and seeds of economic plants likely to succeed in the West Indies are distributed. Mr. Morris left, Kew in November last, and returned home Morris left Kew in November last, and returned home at the end of February. Advantage was taken of his outward journey to send by the same ship, under his innuiediate supervision, a number of Wardian caese filled with Gambier plants. Gambier, it may be added, is the name of a substance used in tanning, obtained from Cincerta Gambier, knob, and the plants had been raised at Kew from seeds received from the Shattas Settlements, several attempts to introduce plants from the East having failed How the plants were successfully carried to the West Indies we learn from the following passage in the

report "Owing to the cold weather, the cases containing the plants on board the Atrato were placed below in the main saloon. There was very little direct light in the daytime, but the question of warmth was for the moment of more importance than that of light. It was also hoped that they could be placed on deck in a day or two at the most The weather during the whole of the first week, however, continued very cold, and it was impossible to expose the plants on deck. Under these circumstances it was fortunate that the electric light, with which every part of the ship was supplied, was available to try an experiment of some interest. Although the plants received very little light during the day, they had a good supply of the electric light during the night, and the plants in the cases more fully exposed to the electric light were afterwards found to be in a much better condition than the others. It is well known that plants will thrive under the influence of artificial light, but in this instance there was so little direct light available during the day, that the plants had to depend almost entirely on the light they pants had to depend amost entirely on the light they received at high. The Gambier plants are particularly sensitive as regards a diminution of light. During the prevalence of fogs at Kew they have been known to drop their leaves within a day or two, and to remain bare during the rest of the winter. This may have been, in some measure, also due to the injurious influence of the

some measure, also due to the injurious imitence or use for fitted. One fitted in the fitted in the

becoming too cold for them on deck, and then the more electric light they have the better.

Out of the whole consignment to the various islands only ten plants succumbed; but this was due to an oversight in carrying the case on to Trinidad and La

sight in carrying the case on to Trinidad and La Gusyra, and having to bring it back again to 5t. Vincent, thereby causing a delay in landing of ten days. Mr. Morris wistled successively Antigua, Dominica, Monsterrat, St Kitts, Anguilla, Tortola, Santa Lucia, St. Vincent, Grenada, Barbados, and Jamanca, being present at the opening of the Exhibition at the last-named sistand. Everywhere the Governors and other officials seem to have done their utmost, both personally and indirectly, to assist Mr. Morris in fulfilling the object and thurrectly, to assist the most are many the mission. Established gardens were inspected, sites for new gardens selected, means discussed, and addresses delivered, from which it is confidently hoped that substantial advantages to the cultural industries may

Mr Morris's Report, which may be obtained for the sum of fourpence, is a valuable and interesting account of the present condition and future prospects of planting in the various islands, and should be in the hands of all concerned. We conclude this notice with an extract from a description of the lime plantations in Montserrat, "where the immense golden heaps of ripe fruit were alone worth a journey to the West Indies."

The West Indian lime (Citrus medica, var acida) appears to be a thin-skinned local variety, little known outside the West India Islands It yields juice of a singularly pure acid flavour, and it deserves to be much better known in this country in the fresh state for making 'lemon' beverages, as well as for general use in cookery The enterprise of the Montserrat Company extends to other things besides limes Nevertheless, from limes alone it is possible to produce a variety of articles more or less valuable. The limes themselves are exported as gathered, or they are preserved in salt water, and shipped in a pickled state for consumption in certain parts of the United States. Lime-juice, obtained by compression, is exported either raw or in a concentrated state. This latter is obtained by evaporating the raw juice in botlers until it is reduced to about one-twelfth of the original bulk, when it is ready for export as a dark, viscid substance like molasses. This is used for the preparation of commercial curic acid From the rind of the fruit, by a process known as 'ecuelling,' which consists of gently rubbing the fruit on rounded projections arranged inside a brass basin, a very fine essence of limes is obtained by distilling the raw lime-juice a spirit is obtained known as otl of limes

NOTES

THE deputation which is to submit to Sir Michael Hicks Beach to-morrow a statement of the facts relating to the pro posed British Institute of Preventive Medicine, will be large, influential, and thoroughly representative of the various depart ments of science. It is expected that the following gentlemen will speak . Sir Joseph Lister, the Duke of Westminster, Sir Henry Roscoe, Prof. Dewar, Mr Haldane, M P. O C. and Prof Ray Lankester. A letter from Prof. Huxley will be read.

THE list of those selected for Birthday Honours includes Dr. Archibald Geikie, on whom the honour of knighthood has been conferred, and Mr Robert Giffen, who has been made C B

In the course of an investigation, part of which has already been communicated to the Royal Society, Prof Roberts-Austen has discovered the most brilliantly coloured alloy as yet known It has a rich purple colour, and bright ruby tints are obtained when light is reflected from one surface of the alloy to another. It contains about 78 per cent. of gold, the rest of the alloy being aluminium. The constants of the aluminium gold series of alloys are now being examined, and will shortly be published

On Tuesday last, at Oxford, Convocation sanctioned the expenditure of very considerable sums of money in order to provide increased accommodation for the medical and science schools. The Lecturer in Human Anatomy, Mr. Arthur Thomson, estimated that the immediate wants of his department necessitated the expenditure of £7000 With this sum might be provided a laboratory, which would include dissectingrooms, a museum, working rooms, and a lecture theatre of a temporary character, and has now proved itself utterly madequate for the requirements of his class The number of students now studying in Oxford with the intention of passing the M B examination is 67 As illustrating the growth of the class, and the interest taken in this school, it may be mentioned that in 188¢ the lecturer's class consisted of only three members The Deputy Professor of Physiology (Dr Ray Lankester) required the more modest sum of £2000 in order to supply the deficiencies in the department of Morphology With this sum two laboratories could be provided, one 40 x 20 feet, and the other 30 × 20 feet Meanwhile the departments of Lithnology and Goology find themselves cramped for space at the University Museum, and Convocation has granted the sum of \$1300 to provide rooms for the use of the Curator and the servants of the Museum, and increased accommodation for teaching The Hope Professor of Zoology (Prof Westwood) needed only the expenditure of £350 upon additions and improvements in his department at the University Muse im The expenditure of these various sums, amounting in the aggre gate to nearly £11,000, will place the School of Medicine and the related sciences in a satisfactory position, and the University of Oxford is to be congratulated on its appreciation of the importance of these departments, and the liberality with which it maintains them

THE Gold Medal of the Linnean Society has this year been awarded to Dr. Edouard Bornet, of Paris, for distinguished researches in botany. His earliest publications related to the structure and life history of Fungi and Lichens, but his name is best known for the important researches in which, with his friend M Thurst, he has been for some years engaged, on the life histories of Algre, and for his valuable contributions on this subject in the "Liudes Phycologiques," and the "Notes Alcologiques," with their beautiful illustrations

At a meeting of the Ashmolean Society, Oxford, on Tune 1, there was an interesting discussion on a paper, by Mr Romanes, on Weismann's theories of heredity, in which Prof. Lankester and Mr Poulton took prominent parts

M Doutton, Denion-trator in Botany at the Museum of Natural History, Paris, has undertaken a scientific expedition to Madagascar.

MR NORMAN LOCKYER, F R S, has undertaken to give a lecture at Bedford College (for Ladies), Haker Street, on Wednesday next, at 4 o'clock, "On Natural Philosophy for Artists"

We regret to have to record the death of Sir John Hawkshaw. FRS He died on Tuesday last at his town residence, Belgrave Mansions, in his Sist year. The greatest of his many engineering feats was the construction of the Severn Tunnel He was President of the Institution of Civil Engineers in 1862-63, and of the British Association at its Bristol meeting in 1875 He received the honour of knighthood in 1873

SEVEN years have elapsed since the first International Ornithological Congress took place in Vienna, under the presidency of the late Crown Prince Rudolph. Eagland was on that occasion, as a correspondent wrote at the time, "conspicuous by her absence," and at the second Congress, which has just been held at Budapest, Great Britain was but feebly represented. It is difficult to understand this unwillingness of Englishmen to visit an International Congress. Our countrymen are always sure of a hospitable reception, the interchange of ideas with foreign colleagues is pleasant and profitable, the personal friendships which result are of permanent value, and in the case of Museum officials the relations established with the Museums of the Continent invariably result in mutual benefit The great question which all coologists can discuss is that of nomenclature This year a prelumnary skirmish took place at Frankfort, where the annual meeting of the German Oralthological Society was held on May 11 and 12, under the presidency of Prof. Wilhelm Blasius, of Brunswick The Senckenburg Museum at Frankfort had been closed for four years, and had been opened to the public only four days before the arrival of the visitors. Prof. Noll, the well-known editor of the Zoologischer Garten, welcomed the German Ornithological Society in a few well-chosen words, and then followed the discussion on zoological nomenclature, which occupied the best part of two days of hard work. The proposals of the Committee appointed to examine into and report on the rules of zoological nomenclature were fully discussed, and were adopted, though, by the courtesy of the members, Mr. Bowdler Sharpe, and Mr Buttikofer, of the Leyden Museum, were allowed to state their objections to some of the propositions. The members and guests of the Society were conducted round the Museum by Prof Noll and Dr Hartert, and great satisfaction was expressed at the excellent condition in which Prof Ruppell's types were found to be The ornithological collection has been carefully catalogued by Dr Hartert, and his recently-published catalogue of the collection is an admirable piece of work. At the conclusion of the meeting, an adjournment took place to the Loological Gardens, where the visitors were hospitably entertained by the Director, who personally conducted them round the Gardens From Frankfort a detachment of members and guests proceeded to Vienna and thence to Budapest, to attend the meeting of the Ornithological Congress

MESSAE MACVILLAN have nearly really for publication "A listory of Human Marriage," by Dr. Rabward Westermarks, Lecturer on Sociology at the University of Finland, Hebitegiors in an introduction pote the work is commended to the attention of students by Dr. A R. Wilkee, who expresses a high opinion of the learning and insight displayed by the author. Dr. Westermark differs widely in many respects from the opinions to the complex of the strength of the property of the strength of marriane.

In the House of Commons on Friday last, there was an interesting debate on the Ordnance Survey Mr. Roby, who introduced the subject, had much to say as to the unsatisfactory rate at which the Survey is proceeding, and Sir George Campbell effectively contrasted the work done in England with that done in other countries In India, he said, the surveys were incomparably ahead of those in the United Kingdom; he was often surprised at the perfection of the surveys even of those portions of that vast country only reached by sportsmen or explorers "In his own country he found nothing of the kind. There, in one of the most cultivated and civilized places in the world, they had nothing but the old survey It was a disgrace to the country that we should not have decent maps." Mr. Chaplin, under whose department the Ordnance Survey has been placed, said what he could in defence of existing arrangements, but was not disposed to deny that there was much solid ground for complaint. He promised that his influence should be used to secure reform in various directions

THE University College Biological Society has arranged for an excursion to Sheerness on Saturday, June 6 The excursion NO. I127, VOL. 44

will leave Victoria at 10 a.m., and the time at Sheerness will be spent either in dredging or shore work. The party will be accompanied by Prof. Weldon.

THE Eastern papers report that an expedition has, by order of the Straits Government, commenced work on the frontier between Burmsh and the Malay Peninsula. Its operations will be chiefly confined to Pahano It is placed under the charge of Mr. Ridley. Director of Gardens and Forests in the Straits Settlements, accompanied by Mr. William Davison, Curator of the Raffles Library, Singapore, and Lieutenant Kelsall, R.A. The funds available for the expedition are 2000 dollars voted from the Straits Treasury The object is to ascend the highest mountain in Pahang, incidentally noting all that can be learned about the physical features and the flora and fauna of the country The expedition was to go by steamer to Pekan, thence up atream to Kuala Lipis, thence northerly up the Tembelinis and Sat rivers I laving ascended the latter river so far as it may be navigable for small canoes, the expedition willstrike through forest and jungle, estimated to extend for sixty miles, till they emerge at Gunong Tahan, which is said to be about 8000 feet high Ascending this mountain, and crossing what is called Cameron's plateau, they will then ascend Gunong Stam, a mountain the height of which has been estimated to be as much as 14,000 feet Having completed this ascent, they will return by the same route, the estimated period of absence from Singapore being between two and three months. The party were to take with them three Tamil hunters and collectors attached to Mr Davison's Museum staff, and three Malays of the Gardens and Forests Department.

At the meeting of the French Meteorological Society on May 5, a discussion by M Millot of fifty years' observations at Nancy was presented. The temperature and rainfall values were divided into two periods, viz. 1841-79 and 1880-90 These averages showed that the mean temperature had considerably decreased since the winter of 1879-80, and that the amount of rainfall had increased, the climate showed a tendency to become more continental M Teisserenc de Bort communicated the results of his inquiries re pecting a destructive tornado which visited the town of Dreux on August 18 last At 10's 5m pm , Paris time, a sharp clap of thunder occurred, followed by heavy rain and hail for about a minute. and five minutes later the tornado broke over the town with a noise resembling that of an express train, making a furrow in the ground, and in less than a minute tiles were flying about, trees uprooted, and several houses destroyed. After a short course the effects of the tornado ceased, and it appeared to rise to the upper strata of air, but descended again with equal violence near Epone about 60 kilometres distant, the rate of translation being about 29 miles an hour. The action of the electricity seemed to be of an unusual nature, although much damage was done by it, no metallic object was fused, but only traces of fusion could be found in bad conducting bodles. Among other incidents an iron bedstead was dismounted, without trace of fusion. The paper was illustrated by several photographs, showing the damage done in various parts of the

DB J HANN has communicated another important treatise to the Vienna Academy, entitled "Studes on the Conditions of All-pressure and Temperature on the Summit of the Sonabilet, of All-pressure and Temperature on the Summit of the Sonabilet, of Sonabilet, of Sonabilet, of Sonabilet, of Sonabilet, of Sonabilet, of Sonabilet, which is based upon four years' and analyzolones." The work is based upon four years' however, the sonabilet of severations, and a sidvided line teight sections, viz.—(1) An investigation of the general meteorological conditions under which the maxima and minima of air pressure occur on the Sonabilet. The anomalies of pressure are more marked above than below, and are increased by the accompanying emperature

THE 4. 18017

anomaly, which is relatively high in barometric maxima, and relatively low in barometric minima. (2) The range of temperature during the passage of a barometric wave. This is, at least during the winter season, the opposite to that at the lower level (3) Temperature with varying amount of cloud in winter. The highest temperature coincides with the least cloud, upon the summit, and conversely on the plain. The clear winter days on the Sonnblick have relatively high temperature with great dryness, and these conditions are characteristic of the harometric maxima. (4) Monthly maxima and minima of temperature. The former mostly occur during barometric maxima, and the latter when the high pressure lies in the west or north, and while a barometric minimum exists over Italy or the Adriatic (5) Temperature and air pressure on the Sonnblick during barometric minima over Central Europe, especially over the Eastern Alps The mean temperature at the height of 6650 feet during the passage of barometric minima was below the normal, amounting on an average to 2° 5 F. during the winter season. The use of deviations of pressure and temperature in answering many questions of atmospheric physics is here discussed, (6) Vertical distribution of temperature, and mean temperature in a column of air of a kilometres in height. The calculations have been made separately for each winter. (7) Preliminary indications respecting the relations of the winddirections to barometric maxima and minima A considerable divergence (45°-90°) is shown from the directions as observed below, and the results confirm the conclusions drawn from cloud observations by 1 A Broun and others (8) Refutation of some objections against the conclusiveness of temperature observations on mountain summits, and general remarks on cyclones and anticyclones. The author points out that recent mountain temperature observations and other facts are opposed to the explanation of barometric maxima and minima in extratropical regions by purely thermic considerations.

THE relations of weather and disease have been recently investigated by Herr Magelsson, of Leipzig, who, having formerly called attention to the nature of certain "waves" which recur in the variations of temperature (distinguishing waves of about 12 days, 50 days, and 18 to 20 years duration), now traces a connection of these with diseases and mortality. The yearwaves especially show this connection, the mortality (in our latitudes) varying with the winter temperature The least mortality (relatively) is at the middle part of the temperature periods. The injurious influence of hest is dominant in the more southern latitudes (such as Vienna), while cold begins to act beneficially In northern places, mild winters prove injurious where several very mild winters come in succession (eg Stockbolm in 1871-74) The most favourable conditions seem to be an alternation of moderately cold and moderately mild winters. Too much importance, the author thinks, has been attached to relative humidity. He further offers proof that infectious disease is even more dependent on weather than disease of the respiratory organs, or arlsing from chill

THE value of systematic observation of snow is now being recognized in meteorology, and in Russia observations were commenced in January last year at 428 stations in the Furopean portion of the Empire, 21 in the Asiatic, and 55 in the Caucasus At first it was simply reported daily whether there was a continuous snow covering about the station or not. But last winter the inquiry has been extended to the depth and general behaviour of the snow. Thus it is expected that in a few years, some valuable climatological material will have been accumulated at St. Petersburg. The report of Herr Berg on the snow in the early months of 1890, in European Russia (Report. fur Metcor), contains a map showing the southern and western limit of the continuous snow-covering for the first and fifteenth of each of the months January to April. In the west the snow extended stea My till the beginning of March, the limit being then close to the Baltic. In the south-east, there was steady advance till F 1 ruary, and as far as the coast of the Casman. In the south, the advance was fluctuating, there being a maximum in the middle of January, and the middle of February, both reaching to the Black Sea coast. The retirement of the snow-limit began in the south and south east in the middle of February, in the west about half a month later. The general direction was north-east. On April 15 the limit passed through Onega on the White Sea. Wetlura. and Kathermenburg

By the first of May, all European Russia was free from snow

Herr Berg describes the weather accompanying the disappearance of the snow, and traces its causation

A DIRECT observation of hail in the process of formation is recorded in the Naturw Rundschau. In the afternoon of a squally day Prof. Tosetti, looking eastwards through the window of a house (in Northern Italy) which, with two others, enclosed a court, saw the rain which streamed down from the roof to the right, cangot by a very cold wind from the north, and driven back and up in thick drops Suddenly a south wind blew, and the drops, tossed about in all directions, were transformed into see halls. When the south wind ceased, this transformation also ceased, but whenever the south wind recurred, the phenomenon was reproduced, and this was observed three or four times in ten minutes

Engineering of the 20th ult. states that an extraordinary accident had occurred at the London Paris Telephone Office in the Palais de la Bourse One of the employes, a gentleman named Weller, wished to communicate with the London office on a matter of service. He had already rung up the English officials, and, the bell having sounded in reply, took up the receivers and put them to his cars, when he suddenly sustained a shock of electricity of such severity that it threw him stappering backwards against the door of the telephone cabinet, which, not having been properly fastened, flew open, with the result that he was thrown heavily to the ground. It appears from inquiries that similar accidents, although less serious, have occurred at this telephone office on several previous occasions. The officials attribute them to lightning striking the wire, either at San Gatte, where the submarine cable ends, or at the terminus of the land wire on the Palais de la Bourse Such accidents, it is declared, might be easily prevented by the simple expedient of erecting lightning conductors at the point where the cable comes ashore, and at the terminus in

In the nineteenth annual report of the directors of the Zoological Society of Philadelphia, attention is called to the unprecedented destruction of many of the more valuable and important animals of the native American fauna, and to the need for the immediate adoption of every means which can be employed to save them from complete extinction The directors think that a good deal may be done in furtherance of this object, both in zoological gardens and private preserves. Of all the bisons now surviving outside the National Park, probably nine-tenths are comprised in a few herds owned by private individuals and zoological societies

A FINE tortoise, weighing 87 pounds, obtained by the U S Fish Commission steamer Albatron, during her recent visit to the Galapagos Islands, has recently been deposited in the Zoological Park at Washington, D.C The specimen was collected by Mr. C. H. Townsend on Duncan Island, and is of much interest, not only on account of the locality it represents, but as showing that Dr. Baur was a little hasty in deciding that Testudo ephisppium is only a synonym of T abingdoni Duncan Island tortoise agrees exactly with Dr Gunther's figure of T. ephippsum, and is entirely distinct from the Abingdon Island species, which is also well-figured in Dr. Gunther's paper. This foure shows a little emargination in the second marginal scute, which might seem accidental, but as it is exactly repeated in the specimen belonging to the U.S Natsor Museum, and as the emargination exists in the bony carapace, it is probably a constant specific character. Dr Gunther gives Indefatigable Island as the locality of T ephippeum, and if thes be correct the species occurs on at least two islands of the group. Besides the Duncan Island Tortouse, examples of T. victus and T. nierita are now living in the Zoological Park, while the U.S National Museum possesses skeletims of T abingdons (imperfect), 7 vicina, and T mgreta The locality of this last-named species is still uncertain, but there is som reason to suppose that it may be from Chatham Island. T migrata has the most arched carapace of any species, T. chistisum and T abingdons the longest and anteriorly most compressed and elevated carapaces. Between these lie in the order named T. manothyes and T vising. There is a direct correlation between the anterior height of the earnpace and the length of the neck, the rule being the higher the carapace the longer the neck. T' merita and T abinedoni having respectively the shortest and longest necks. Mr Townsend writes that tortoises are now extremely rare on Duncan Island.

This pine number of the Zologene contains an Interesting paper on the habits of the moves, by the J. G. Lockhatt. One of the points noted by the author is, that mose generally he with the tail to wardward, training to their senses of being and wriding, which are remarkably sents, to warn them of the word of the contraction of the contraction of the word in the contraction of the word in the contraction of the word in the contraction of the word them for midgate to least, where herming, and especially smelling, would be of little use. While they are sepling or chewigh to ed, their care as an paperpain linear, one landward, the other forward, alternately. They also have the remarkable in neight to make a short turn and sleep below the ward of their freel track, so that suppose failing thereon and following at pin sum to be heard or small before he can get deposing at pin sum to be heard or small before he can get

Ms L. Urcorr G11. has published as a pumphlet appared by the Rev II A Somet blooch the Bonnley Naturalian's Society on the scientific measurement of shildren Mr. Somes says he finds such measurements as he describes, taken every term, a good guide as to whether his pupils may be pressed until work or not. "If the increase is regular and the weight fair, escending to the height, I do not fair to press them, lust for most other hand, the weight so weight allow, or the height increases and the other hand, the weight is low, or if the height increase in the side with the side of the side of

THE first volume of Sir William Thomson's "Popular Lectures and Ashireuses" (Mommillan), has rasched a second collition. The third volume has also just been published, and the author hopes that the second volume may appear in the course of a year or two.

THE new number of the Journal of the Anthropological Institute (vol. xx, No. 4) peens with a paper in which Lady Welby calls attention to what she calls an apparent paradox in mental evolution. The number also includes a paper, by Mr. F. W. Rudfer, on the source of the just used for accept implements in Europe and America, and the Presidential address delivered by Dr. Beddoce.

THE B Manical Society of Edinburgh has issued the eighteenth volume of its Transactions and Proceedings. Dr. Antchson's "Notes on the Products of Western Afghanshan and of North-Eastern Persis," forming the first part of the volume, may be obblinded separatie."

Two new parts (62 and 63) of the elaborate dictionary of Chemistry included in the "Encyclopaedie des Wissenschaften" NO. 1127, VOL. 44] (Bresian: Eduard Trewendt) have appeared. The eighth part of the hand-book of Physics, in the same Encyclopedia, has also been published.

This midst edition of "Telegraphy," by W. H. Preces and is. Sleweight (Congman), has been published. The edition is described as "slmost a new book." No fewer than 24 figures have been altered and 44 excluded. On their are now affe as compared with 1941 in the last edition. The authors have aliand at "providing new a general introduction to the art and scarce of "providing new a general introduction to the art and scarce of the state of the st

Messas Longmans, Green, and Co are issuing the tenth edition of Quant's "Elements of Anstomy". It will appear in three volumes, and a being edited by Prof. E. A. Schafer and Prof G. D. Thane. The second part of the first volume—by Prof Schafer—has just been published. The subject is general anatomy or histology.

PART 32 of Cassell's "New Popular Educator" has been published. Besides illustrations in the text, it contains a coloured map of Switzerland

THE Geological Survey Department of Canada has assed the first of a series of descriptive and liturated quanto memorato not the Vertebrata of the Tentary and Certaceous rocks of the Canadan North West Territory, peapered for the Survey by Foof E. D. Cope, of Philadelphia The Report is devoted esclusively to a combieration of the species from the Industry Misconia deposits of the Cypress Hilly, in the district of Alverta, and consists of severy-seven pages of letterpress, tiliastrated of Alverta, and consists of severy-seven pages of letterpress, tiliastrated with control of the Vertebrate of the Vertebrate of the Laramse formation of the North-West Territory, by the same author, in now in cornes of preparation.

Mx Percy F Kendall has prepared a little volume ennitide "Hints for the Gudance of Observers of Useral Geology " it is intended to serve as an oniver to the request for gudance which have been made by members of the North-West of England Boulder Committer. The work is printed only on alternate pages, so that students using it will have space for occisional lived notes

"An approved Treatuse of Itawks and Ilawking by Edmind Ben," Info, has just been reprinted, with an introduction by Mr. J. E. Harting. It is the rarest of English books on falcony, and no copy has come into the market for early teenty years. The reprint is an early in facunitie as it is possible to make it without the and of photography, and a number of the market for the control of the property of the property

INDIGOCARMINE, the commercially important disulphonic acid of indigo, has been synthesized in an extremely simple manner by Dr Heymann in the laboratory of Messrs. Bayer and Co. of Elberfeld, and a description of the mode of operation is given in the new number of the Berichte The reaction merely consists in acting with excess of fuming sulphurle acid upon phenyl glycocoll, C₆H₃-NH-CII₃-COOII, the aniline derivative of glycolle acid. When a quantity of fuming sulphuric acid is poured upon a tenth of its weight of phenyl glycocoll in a test tube, the phenyl glycocoli rapidly dissolves, the acid becoming coloured vellow and slightly elevated in temperature. while sulphur droxide commences to be evolved. If the solution is then poured over ice the greenish blue colour of indigocarmine is at once obtained The best conditions for working the process on the large scale are as follows. One part of phenyl glycocoll is mixed with ten to twenty times its weight of fine sand so as to avoid local superheating during the process of addition to the fuming scid. The mixture is then introduced into about twenty times its weight of fuming sulphurie acid at a temperature of about 20°-25° The fuming acid should contain at least 80 per cent of sulphuric anhydride, and the temperature should be so controlled that it never exceeds 30° during the process of adding the mixture The yellow solution thus obtained vields instantly the blue coloration due to indigocarmine on removing the large excess of sulphuric anhydride by the addition of ordinary oil of vitrol, sulphur dioxide being evolved. Upon further diluting with ice and addition of common salt (indigo earmine being more difficultly soluble in salt solutions than in pure water) the colouring matter is precipitated, and may be readily isolated. The product thus obtained is found to consist of nure indigocarmine The tints obtained with this product are vastly superior in beauty and, clearness to those obtained with even the better kinds of commercial indigocarmine, on account of the higher degree of purity attained by this mode of preparation. The chemical changes occurring during the process appear to be as follow. The first product of the action of fuming sulphurte acid upon phenylglycocoll appears to be the

This substance, however, is unstable, and decomposes upon the removal of the excess of SO, into indigo disulphonic acid. sulphur dioxide, and water, probably according to the following equation-

$$2SO_{0}II - C_{0}II_{2} \\ SO_{0}II - C_{0}II_{2} \\ NII \\ SO_{0}II - C_{0}II_{2} \\ NII \\ C = C \\ NH \\ C_{0}II_{2} - SO_{0}II \\ SO_{0}II - C_{0}II_{2} \\ NII \\ C = C \\ NH \\ C_{0}II_{2} - SO_{0}II \\ SO_{0}II_{2} - SO_{0}II \\ NII \\ C = C \\ NH \\ C_{0}II_{2} - SO_{0}II \\ SO_{0}II_{2} - SO_{0}II_{2} \\ SO_{0}II_{2} - SO_{0}II_$$

Of course the most important point of commercial interest about a new reaction is the yield, and in this respect Dr. Heymann is very fortunate, for already 60 per cent of the theoretical has been attained The process has consequently been patented by Messrs Bayer and Co, and appears likely to become a very successful onn

THE additions to the Zoological Society's Gardens during the ast week include a Water Buck (Cobus ellipsipsymmus ?), a Leopard (Felis fardus), two Vulturine Guinea Powls (Numida vulturina), two Mitred Guinea Fowls (Nunnda mitrata) from East Africa, presented by Mr G. S. Mackenzie, F & S., a Peregune Falcon (Falso peregunus) from Scotland, presented by Mr Thomas C Smith , a Mountain Ka-Ka (Nester notabilis) from New Zealand, presented by Mr Herbert Furter, a Grey Squirrel (Sciurus griscus), a Squirrel (Sciurus sp. inc.) from North America, a Ducorp's Cockatoo (Catalua ducorper) from the Solomon Islands, pre-ented by Mr Nicholas O'Reilly , two Ravens (Corous cosas) from Ireland, presented by Captain Ogdby, a Cheetah (Cynclurus jubatus) from Persia, three Blandford's Rais (Mus blandfords), two --- Terrapins (Clemmys sp inc) from India, deposited , two Coypus (Myofotamus coypus) from South America, two Andaman Starlings (Sturma andamanensis) from the Andaman Islands, two Redbilled Hombills (Inccus crythrorhynchus), two African White Spoonbills (Platalea alba) from Africa, two Virginian Engle Owls (Bubo virginianus) from North America, purchased, a Red Deer (Cervus elaphus &), a Japanese Deer (Cervus sika Q), born in the Gardens

OUR ASTRONOMICAL COLUMN.

THE MERIDIAN PHOTOMETER.—In vol XXIII, of the Annals of the Harvard College Observatory, Frof. E. C. Pickering and C. Wendell give and discuss the observations made at Cambridge, U.S., with the meridian photometer during the years 1892-88. The observations relate principally to stars north of

NO. 1127, VOL. 44]

the declination - 40° Vol. xiv. of the Annals contained the the declination -40° vol. xiv. of the Annais contained the results of observations of the brightness of stars made with a small meridian photometer. The present volume deals with the photometric measurements of somewhat fainter stars, made by means of a similar but larger instrument

REPORT OF HARVARD COLLEGE OBSPRVATORY—Prof Pickering has just issued his Report for last year. He again urget the necessity of a fire-prof building for storing the 27,000 photographic plates of spectra, 9000 of which were taken in 1890. Legacies for the endowment of science in America are so common that it is not surprising to learn that the Observatory has received a gift of 25,000 dollars through the the Observatory has received a gift of \$5,000 dollars through the take Mr J I Bowditch During the past year; 1500 photolate Mr J I Bowditch During the past year; 1500 photonoise at the station near (I osses, in Peru. Nertly all of them
relate to the region ostul of -20 Mr. Draper has added
another instrument of the same kind to the Henry Draper
Minorial. This is mounted in the Observatory grounds at
Cambridge, and since September 1850, 2137 photograph
have been taken with a, covering the sky north of -20 Mr.

By the state of the same the state of -20 Mr.

T placing a prism of small angle over the objective, the spectra of stars as faint as the tenth magnitude have been obtained. Ser stars as fant as the tenth magnitude have been obligated. See such Type IV, spetch shaw been discovered: Spectra stars, with Type IV, spetch shaw been discovered: Spectra the phylogen time F isas been abown to be bright in eight intercept, there having been added to the list during the perty caph, three having been added to the list during the perty which the hydrogen hies are bright at maximum. This peculantly has furnished a means of discovering seven new variable stars. The 11-and, beleacep has here not for a default which yet a star of the star of of the spectra of the brightest stars, with the result that B Aurige and CUrse Majoris have been discovered to be close binaries One photograph of or Herculis seems to show that this star also is double, but this has not been confirmed. With the 12-inch telescope a number of "canals" on Mars have been recognized, but only one of them was distinctly seen to be double. An important accession to the white spot surrounding the southern pole was found by photographs to have occurred between the nights of April 9 and 10. The Report concludes with a list of the numerous publications issued by the Observatory during the vear

THE SOLAR PARALLAX AND IIS RELATED CONSTANTS.

I would be difficult to conceive a more masterly and comprehensive exposition of astronomical and physical constants than one just issued by Prof W. Harkness, of the United States Naval Observatory As is rightly pointed out, "The solar Naval Observatory As is rightly pointed out, "The solar parallax is not an independent constant. On the contrary, it is entangled with the lunar parallax, the constants of procession and nutation, the parallactic inequality of the moon, the lunar inequality of the earth, the masses of the earth and moon, the ratio of the solar and lunar tides, the constant of aberration, the velocity of light, and the light equation." It should therefore be determined simultaneously with all these quantities by means of a least square adjustment, and Prof Harkness develops such The equations connecting the constants are given, whilst the numerical values which are discussed are based upon n enormous mass of astronomical, geodetic, gravitational, and tidal observations which have required more than two hundred years for their accumulation. The sources of prohable error are also examined, and it is suggested how some of the constants may be improved in the future. The completeness of the lists of constants, and the careful manner in which they are discussed and corrected by the comprehensive least-square adjustment which is developed, justifies our giving serialist the results obtained — Equatorial semi diameter of the earth-

Constant of aberration-

20" 45451 ± 0" 1258. NO. 1127, VOL. 44] The time taken by light to traverse the mean radius of the earth's orbit (the light equation)—

498'00595s. ± 0'30834s.

The velocity of light in vacuo per second of mean solar time— 186337.00 ± 49.722 miles

In order to imbrove the system of contains sile-raned, Prof. Hardness thinks have the system of contain should be destrained by the disural method at one or more stations as near as possible to the equator, and that the Observationes in the northern and southern hemspheres should so-operate with each other for not some stations and the state of the state

The laborous character of an investigation which leads to the results here given is patent to all. To say, therefore, that all the computations involved were made and checked by Prof. Harkness himself is to testify to industry very rarely excelled.

TECHNICAL EDUCATION IN RUSSIA.

An interesting report on technical education in Russia has been laid before Parlament by the Foreign Office. It is a digest by Mr. Hafford of a very olumnous Report, compiled by Mr. Anopost, Director of the Nicholas Industrial School at S Feterbarg, on technical education in Russia, and is described by Sir K. Monter agiring an extensive review of all the properties branch of the state of the

schools about to be founded.

M. Anopoff contineth himself to giving full testals of intermonatorism, without attempting a description of the higher
institutions, without attempting a description of the higher
schools. The cubhishment of these former classes of schools
dates, he says, from only young 25 years hack, but in that short
dates, he says, from only young 25 years hack, but in that short
leads to be a second of the second of the second classes of schools
dates, he says, from only young 25 years hack, but in that short
to be a second of the secon

sects exclusively connected with railways, no account of them is given. (3) Industrial schools with a course of general education not exceeding the scope of the course of primary schools, or sometimes reaching the standard of the second class in village sometimes reacting the standard of the second class in village schools with two classes. In most of them pupils are received who have completed the course in the public school, and who repeat what they have gone through in it. These schools are founded with the object of preparing skilled artisans for village tounces with the object of preparing skilled artisans for village and domestic industries, and also factory hands. They contain workshops for joiners, blacksmiths, carpenters, fitters, tailors, shoemakers, saddlers, bookbinders, &c, but few of these institutions can boast of a systematic course of instruction in trades (4) To this group belong various special and general educational schools for adults, as the school for foremen builders, the school sidoots for adults, as the school for foremen builders, the school for printers, the evening and Student special classes of the Imperial Technical Society at St. Petersburg, the Rigg. Industrial School, &c. The teaching in these institutions takes place in the evenings of week days, and on Studeys, s. s when the adult workmen for whom they are intended are free from their work. (5) This group consists of elementary schools of general education, s. s. printers, datrick, or municipal whools with supplementary industrial section I. 18 wordly for date that person of the students of the schools of these schools of the schools of t certain standard, at any of the schools of these five groups, enjoy certain privileges with regard to exemption from military service The report then goes on to describe in detail the courses of some of the leading industrial schools as types of the different groups, as well as of the industrial classes attached to the elementary schools In conclusion, the report summarizes the more important provisions of the ukase of March 7/19, 1888. reschools may be opened in Russia, either wholly or in part, as the expense of the State (given in Appendices I, II, III) The cost of maintenance of these schools is respectively estimated in cost of maintenance of three schools at respectively estimated in the usase in follow the intermediate incchanneal technical schools at 27,311 (2735) per annum, the elementary mechanical technical schools at 19,450 (2756) per annum, and the trade schools at 11,950 (2750) per annum. The Ministry of Folusion has assigned for this year the sum of £50,000 for the creation of these technical schools, and it is reported that the Ministry has been urged to devote a consider reported that the atinistry has been urged to devote a consider able portion of this sum to founding schools in the districts where village industices prevail, the richer manufacturing districts being better able to dispense with State aid. The provisions of the ukase are —(1) The industrial schools for the male inhabitants of the Empire exist for the purpose of diffusing among the population technical education of the intermediate and elementary standards, as well as instruction in handreafts. ementary standards, as well as instruction in handicrafts and elementary standards, as well as instruction in handicratis (2). The intermediate technical schools impart the instruction and skill indispensable to artificers who are destined in time to act as the trusted assistants of sequencers and of other managers of industrial enterpraces (3). The elementary technical schools, besides intermediate on the time of the control of the co definite handicraft, likewise impart the knowledge and skill indispensable to men whose duty it will in time become to act as indispensable to men whose duty it will in time become to act as master-workers and immediate overseers of the operations of artisans in individual consistence of the operation of artisans in individual consistence intrins in the methods of any one trade, and at the gracuate intrins in the methods of any one trade, and at the gracuate intrins in the methods of any one trade, and at the gracuate intrinsical consistence of any one trade, and at the gracuate interest in the interest in the consistence of any one trade work of such trade. (5) Industrial schools of each of the above-mentioned categories and east either apart or conjunction with other similar schools of various degrees and (7) The industrial schools are supported at the expense of the Crown, or of the sensitives, societies, guilds, or private individuals, or by funds contributed simultaneously from all these sources (8) The course in the intermediate technical schools is not to exceed four years; that of the elementary and trade schools three years (9) Those who enter trade schools are required to produce a certificate of their having gone through the course of an elementary school, those who enter the elementary technical schools, a certificate of having gone through the course in a municipal school, or village school, with two classes, while in a ministryal school, or village school, with two classes, while those who enter intermediate technical schools must have gone shrough five classes of a Kraitziuli. (10) Those who are unable to satisfy the conditions mentioned in the preceding paragraph, but who have worked not less than two years in industrial institutions, and have proved that they can successfully follow the course at the school they wish to enter, may be also admitted. (11) Industrial schools must have (2a is library, 0b) a room with

appliances for geometrical and freehand drawing, (c) where possible a room with appliances for modelling, (d) the necessary methods and appliances for modelling, (d) the necessary methods, and in addition the requisite appliances for the practical work of the apprentices (14) Fupils who have exceedibly empleted their effection in an intermediate techniques of the second of the after three or two years respectively, spent uninterruptedly in industrial work. Those who are so styled obtain certain privileges as regards their civil status and in respect to military service, and they emoy in addition the right of entering the higher technical schools Those who have completed the course at the other two categories of schools enjoy the privileges as regards civil status and military service which correspond to the general education they have received

FOSSIL FISH OF THE SCANDINAVIAN

MR DAVIS his availed himself of the opportunities pre-sented to him by the chief officers of the Museums of Lund, Stockholm, and Copenhagen, and has published a mono-graphic account of the fish remains from the Cretaceous formations of Scandinava

Over seventy years ago Sven Nillson first discovered fish re mains in the Swedish chalk S.nce then numerous large collec tions have been made by the officers of the Geological Survey of Sweden and others, and the greater number of these specimens Sweden and others, and the greater number of these specimens were unreservedly placed at the disposal of Mr Davis for description in his memoir, he has also had the opportunity of consulting some smaller collections in Sweden, and most of the forms have been figured from the original specimens by Mr Crowther These fish remains show a closer relationship to the Cretaceous

"These fish remases show a closer relationship to the Createcous fish remains of the north of Europe, as represented by the English and French chalk fish, than to the more highly specialized chalk fish under James Marion, but they do not afford the control of c and of that of Central Europe generally, whilst it affords com-paratively few data for comparison with that of Lebanon The paratively few data for comparison with that of Leonanon 1 ne occurrence of numerous tech of several species of Scapano-rhynchus in the Swedsh area is worthy of note, but the fish are not found preserved bothly as they are in the clusk of Lebanon This memor is published as Part vi. of vol 1 v. of the Transactions of the Royal Dublin Society, and is illustrated

with an atlas of nine plates.

SOCIETIES AND ACADEMIES. LONDON.

Royal Society, May 28.—"On the Bases (Organic) in the Juice of Flesh Part I" By George Stillingfieet Johnson, M R.C.S., F.C.S., F.I.C. Communicated by Prof. G. Johnson,

The author has endeavoured to ascertain by careful experi-The author has endeavoured to ascertian by careful experi-ments how fast he substances thirteen prepared from field have re-ment how fast he substances thirteen prepared from the ducts, due to (1) the science of absumed or physical agencies, applied in the course of extraction, or (2) to bacterial scition modifying the composition of the flesh before it comes into the The final conclusion drawn is but ascroak tractice is not present in fresh muscle, but results from bacterial action whereas ascroak extraints is probably a true "deuch action"

Chemical Society, May 7,—10; J. H. Gitchtone, F.R.G., Vice-President, in the chair,—The following papers were read,—The action of alkalis on the nitro compounds of the paraffia series, by W. R. Danstan and T. S. Dymond. The paper contains the results of further investigation of the inter-action of alkalis and nitroreshine, of which a perfumery account acieno o alkalis and nitrochane, of which a prelimancy acousts have already been given (Chem. Soc. Proc. 1835, p. 12).

Late already been given (Chem. Soc. Proc. 1835, p. 12).

Carbon dioxide, and the alkali derivative of nitrochane, which is obtained when alkali hydrocide is employed. Amounts compound, to be the with nitrochanes in the cold to form a crystaline compound, of alkali proceeds further on warming, and there are formed alkali intritic, accommending the compound, boiling at 171, and solidlying to a crystaline mass when cold to 3'5. The authors fin I that this compound is trimethylisoxazole

It is very stable, and is almost unaffected by heating in closed It is very stable, and it almost unaffected by heating in closed tubes with strong acids and aliasis. Permanganae conducts it to accuse and oralic archia. By credening agents it is abovely decomposed with formation of annotations of an experimental accuse and accuse and oralic archia. By credening agents in 100 pt of 100 pt acted on by alkalis, yields triethylia xxaole, propionitrile, and alkali nitrile, but the reaction occurs with greater difficulty than in the case of nitroelihane. Nitromethane is readily acted on by alkalis, and hydrogen cyanide, alkali intrite, and much resun are formed. The parent noxable could not be isolated. Secondary, and the statement of the parent noxable could not be isolated. are formed. The parent hoxazone could not be assisted occupa-ary nurropropane is attacked with difficulty by alkalis, and no isoxazole is formed .—Some new a idition compounts of this carbande which afford evidence of its constitution, by J E keynolds, F.R.S. Thiocarbands combined with the constitution of the carbands combined the combined combined combined the combined combined the combined combined combined the combined combined the combined Thlocarhamide combines with ammonium bromide, todide, and chloride at the temperature of boiling alcohol, and forms compounds of the type (H4N,C5),H4NR. Under the conditions specified no compounds were obtained Onder the conditions appearance in compounds were containing less than four molecular proportions of the amide to one of the ammonium haloid salt. M-thyl, ethyl-, allyl-, phenyl-, diphenyl , and acetylphenyl-thiocarbamides do noi phenyl; appenyl, and acetylphenyl-thiocarbanides do not yueld compounds with amm nium bromide at the temperature of boiling alcohol Thiocarb mide and tetrethylammonium bromide and todde yield compounds of the type (H,N,C),Ft,NR Under the experimental conditions, no well defined substance and solded yield compounds of the type (II,N,C.),P(,N,N). Under the expressional conditions, no well desided substance was obtained containing more that two molecular proportions was obtained containing more that two molecular proportions of the containing more than two molecular proportions of the containing and the compound (II,N,C.),NeII,NII: Thocarbamide, when treated with relevant more than the compound (II,N,C.),NeII,NII: Thocarbamide, when treated with relevant more than the compound (II,N,C.),NeII,NII: I does not, however, combine with chylamonium brounds; and when heated with the sait in the compound (II,N,C.),NeII,NII: I does not, however, combine with chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and when heated with the sait with alcohol, it yielded elip) coules and either than the chylamonium brounds; and when heated with the sait in the chylamonium brounds; and with alcohol, it yielded elip) coules and either than the chylamonium brounds; and with alcohol, it yielded elip coules and tentum of the chylamonium brounds; and with a chylamonium brounds; and with the chylamonium brounds obtained. Prolonged heating produces a secondary re-

NO. 1127, VOL. 447

action expressed by the equation R.NCS + CH₂COOH = CH₂CONHR + COS. In the case of fatty thiocarb-amides a well-defined acctylated thiocarbamide is first produced, amilies a weit-tennice accipiance information of missard oil, and prolonged heating gives rist information of missard oil, but the yield of the latter is never high, and as final product a substituted amide is produced—The decomposition of silver chloride by light, by A. Richardson. When pure silver chloride is exposed to light under water oxygen is evolved, part of which is present as ozone, when small quantities of water are present, chloring and hydrogen chloride are found in solution, with large chlonne and hydrogen chlorule are found in solution, with large quantities of water, hydrogen chloride, but no chlorine, is found. The influence of hydrogen chloride in restanting the decomposition of silven chloride is considered, and is explained from extended to the control of hydrogen chloride exercise a marked influence on the stability of chlorine water when exposed to thigh, the rate of decomposition of the silver chloride being dependent on the readiness with which the chloride being dependent on the readiness with which the chloride is notion to always and water interact to form hydrogen chloride. The author describes exprenents which should be controlled to the chloride controlled to the c to light contains no oxygen, and he concludes that it is of the nature of a sub chloride rather than an oxychloride.—The addi tion of the elements of alcohol to the ethereal salts of unsaturated tion of the elements of alcohol to the elements again of unsaturated acids, by T. Purdte and W. Marshall The authors record the results of experiments on the addition of the elements of alcohol to ethereal salts of fumaric and maleic acids by the agency of small quantities of sodium nikylate, they also describe a scries of experiments with other ethereal saits, the object of which was to ascertain if the ethereal saits of unsaturated acids in general are capable of undergoing the same additive change general are capable of undergouag the same additive change by the action of a small quantity of ordium methylate in the cold and the same of the attaches itself to the β -carbon atom. Ethylic methacrylate also formed additive compound, but pure products were not obtained formed additive compound, but the products were not obtained methylic and ethylic cimanast ϵ and ethylic ϵ (β) ethyleumants do not undergo additive change.—Noise on the axo-derivatives of β naphthylamine, by R. Meldola, F R S, and F Highes The authors have completed the series of an oderwatives obtained to the series of an oderwatives of the series of the series of the subcess that the series of an oderwatives of the series of the subcess that the series of an oderwatives of the series of the series of an oderwatives of the series In author's have completed the series of all overvaires outlinable from the intrainines and β naphthylamine by preparing orthonitrobenzene alo β naphthylamine. The latter by the action of nitrite in a warm actic acid solution gives orthonitrobenzenesco β-naphthol. In cold alette acid solution the naphthyl acctate is formed. Actyl derivatives of the the naphthyl acetate is tormed. Accept derivatives on me orthor, meta, and para-infrozac-derivatives of \$\textit{\textit{m}}\$-apphthylamine have also been prepared. The pseudazimides from the para and metanitro compounds have been prepared. These

compounds have the formula $C_{10}H_{\bullet} \stackrel{"}{\underset{N}{\bigcirc}} N \cdot C_{\bullet}H_{4} \cdot NO_{\bullet}$ (p or m). The action of aldehydes on these B naphthylamiae azo-derivatives gives rise to the formation of triazines, which aco-derivatives gives rue to the formation of trainies, which are being investigated —A method for the eximation of intrains, are being investigated in the control of the

Linnean Step in the chair—The Tensurer presented his
Annual Report duly sudied, and the Secretary having associated
the elections and death during the part twelve month, the susal
ballot took place for new members of Council, when the followLister, St. G. Mayrat, and F. W. Oliver. The Fresident and
officers were re-elected. The usual formal business having been
canasacted, the Freedent proceeded to deliver his annual address,

taking for his subject "The Secondary Sexual Characters of Admands and Plants," of which he gave several interesting examples, illustrating his remarks with graphes sketches in coloured chafts. On the motion of Mr. H. Druce, seconded by Mr. C. Tyler, a vote of thanks was accorded to the President for his able address, with a rangest this has more?" Typer, a vote of thanks was accorded to the President for his able saddees, with a request that he would allow it to be printed.— The Lannean Society's Gold Medal for the year 1891 was then formally awarded to Dr. Edouard Bornat, of Paris, for his researches in botany, and on his behalf was presented to M Raymond Lecomte, Secretary to the French Embassy The proceedings then terminated.

Institution of Civil Engineers, May 26.—Annual General Meeting.—Sir John Coode, K.C.M.G., President, in the chair—In the Report of the Council for the session 1890 91, it was —In the Report of the Council for the session 1890-91, it was remarked that the salient feature of the session, now term-nated, had been the realization of a proposal made more than forty years ago—namely, the formal reception by the President and Council on stated evenings after the ordinary meetings of the members and visators then present. A sense of recognition was hald after the ordinary meetings in the months of January, when the ordinary meetings in the months of January, and the ordinary meetings of the present and the present and the present and the present and to the models and other objects of motted to be present and to the models and other objects of motted to be present and to the models and other objects of motted to be present and to the models and other objects of the motted to be present and to the models and other objects of the motted to be present and the present of the motted to be present and the present of the present o the members and visitors then present. A series of receptions the roll of the Institution during the past year was 247 The number of members of all classes, students excepted, on March number of members of an classes, students excepted, on march 33 last, was 5150, as against 4903 on the same day last year, representing an increase at the rate of 5 per cent.—The adoption of the Report was moved, seconded, and carried, and it was ordered to be printed in the Minutes of Proceedings Cortial votes of thanks were then passed to the Prescuellent, to the Vice-Presidents and other Members of the Council, to the Auditors, to the Secretaries and Staff, and to the Scrutineers -Addition, to the Seatisties and Staff, and to the Seatisties. The ballot for Council resulted in the election of Mr, Leorge Berkleya Prendent, of Mr. H. Hayter, Mr. A. Gales, M. P. Sitt. Programs Back, C. M. G. J. Wolfe Barry, Mr. E. A. Cowper, Sir Jan N. Douglass, F. R. S. Yose-Pre-duction, and of M. W. Househaw, Mr. A. M. Charles Seating of the Council Results of bers of the Coulect — a necession was adjourned until the second Tuesday in November, at 8 p m [At the first meeting of the newly elected Council, the following officers were re appointed Mr H L Antrobus, as Treasurer, Dr Wm Pole, FRS, Honorary Secretary, and Mr. James Forrest, the Secretary]

EDINBURGH. Royal Society, May 4—Sir Dougles Machagan, Presilent, to the chair—A preliminary note by Mr. John Aitken, on a method of observing and conting the number of water particles in a fog, was communicated. The phenomena which are denoted by the names fog, mat, and ran, differ merely in cleaning the name for the control of the phenomena which are in the name for the present the present in the art to a greater of as seen. The haze turns into a fog degree, and not in sino.

In a naze dry dust particles are present in the air to a greater or less extent. The haze turns mino a fog when water vapour is condensed upon the particles, and the fog will develop into mist upon the condensation of a sufficient amount of moisture. So that we may regard an ordinary fog and a mist as a dry fog and a wel fog respectively. The water drops in a fog will gradually settle upon the exposed surfaces of bodies. Hence it might seem that, in order to determine the soules. Hence it mignt seem tank, in order to determine the extent to what mossture is present in a fog, it would be sufficient to allow the drops to fall upon a piece of mirror, which they would soon wet. Met M. Aitken has found that when exposed surfaces are quite dry, a great quantity of water drops are often present in the air. The drops are exceedingly small fault evaporate with great rapidity from the surfaces (heated by the company of the present that the present the surfaces these of the present that the present the present the present the present the present that the present the by radiation) upon which they fall. The instrument which Mr. Attien has adopted for the purpose of determining whether or not water drops are present is essentially identical with his pocked-usic counter. It consists of a glass micrometer divided into equates of a known axes, a spoj mirror for illuminating the expense of the control o

working with a magnifying lene. In one fog which was ob-served, objects at a greater distance than 100 yards were quite invisible, and the surfaces of exposed objects were quite dry. The number of drops which fell jer minute varied greatly, sometimes reaching 3000 per square centimetre, sometimes only
300 per square centimetre
Two days later the same apparent 300 per square continuere Two days later the same apparent external conditions regarding fog again obtained, and the number was found to be 1300 per square centimetre per minute number was found to be 1300 per square centimetre per munute—which remained fairly constant until the fog began to clear off when it slowly diminished. In both cases the observation was made at to a m. If the stage be slightly heated, the drops never teach the surface but evaporate in the layer of bested at over it. Mr. Aitlen has slow modified this apparatus in order over it. Mr. Aitlen has slow modified this apparatus in order to admit of the counting of the number of drops which fall from to admit of the counting of the number of drops which fall from a column of air of known height. A low power microscope is used, and so a column of air 3 centimetres long can be obtained over the stage.

Underneath, and concentric with the nucloseepe, a tube 5 centimetres long and 4 centimetres in diameter is mounted. The top and bottom of this tube can be simulaneously closed by covers which turn on an axis parallel to the necessary closed of covers when turn on an axis parallel to the axis of the tube. A micrometer, illuminated by a spot mirror, is fixed in the centre of the bottom, and, in the centre of the upper cover, a small opening which corresponds to the lens of the microscope is made. The former instrument may be seed to observe the larger particles or disas in the stimospher.—1):

MAMMALS LIVING AND EXTINCT

An Introduction to the Study of Mammals Living and Extinct By W H Flower and Richard Lydekker (London Adam and Charles Black, 1891.)

THIS work is, as the authors inform us in the preface, based largely upon the article Mammalin, together with forty shorter articles, written by Prof Flower for the minth edition of the "Encyclopedia Biratanica". Certain other articles by Dr. Dobson and Dr. St. George Mivart have also been made use of. The illustrations, most of which are admirable, are chiefly those prepared for the "Encyclopedia." but many have been added Mr. Oldfield Thomas, of the British Museum, the sassisted the authors in special matters. To Mr. Lydekter fell the task of arranging the various articles made use of in proper sequence filling up gaps and adding new matter, a large amount of which treats of the extract forms.

The book resulting from this process is undoubtedly now which will be found interesting and useful by ail students of soology. There is a great deal in it which is worth reading, esperially, so are the four introductory chapters on general anatomical characters, origin and classification of the Mammalia, and on geographical and geological distribution. Moreover, with regard to important animals such as the lones, sheep, goat, jug, a great deal of accurate information of varied character is given. The whiles are, so we should expect, treated given in the state of the stat

It should, however, be clearly understood that the book is not and does not profess to be a complete work of reference on the Mammalia. The references to extinct groups are exceedingly scanty, and whilst they serve to stimulate the reader's desire for further information, do not, as a rule, furnish him with the titles of original works in which such information is to be found. The bulk of the work Cousists of chapters treating of the orders of Mammalia in systematic sequence, and there is no doubt that, both for the general reader and for the more technical zoologist, they form a mine of valuable information well up to date, and as a rule well set forth by the aid of illustrations As an example of the latter, I may refer to the excellent woodcuts of the skull of Tritylodon from the Trias of South Africa, and of various lower jaws illustrating the section on Mesozoic Mammalia, but additional figures of this most important and little known series of forms would have been welcome, and one reads with unferened disappointment the declaration that "it would be beyond the scope of the present work to describe in detail, or even to mention the names of, all the members of this group"

There are one or two points of general interest in the earlier chapters to which I may briefly call attention

The view originally formulated by Huxley, that in looking among Vertebrates for the progenitors of the Mamalia we must pass over all known forms of birds and reptiles and go right down to the Amphibia, is maintained

by the authors, whist reconcining this conclusion with Prof Cope's important observations on the remarkable resemblances which obtain between the extinct reptiles known as Theoromorpha (Therodonia, Pelycosaura) and the Monotreme Mammals Recent observations have shown such an intuinate connection between the South African Theromorpha and the Labyrinthodoni Amphibans that there can, our authors maintain, be no hesitation in regarding the one group as the direct descendant of the other and "we may probably regard the Mammalia is having originated from the same ancestral stock at the time the Amphiban tripe was assing into the Rootlian."

In reference to classification, the authors observe that it is a simple matter to indicate natural groups, such as orders and sub-orders, among existing Mammals, but when we pass to the extinct world all is changed. New forms are discovered which cannot be placed within any of the existing divisions "Our present divisions and terminology are," say I'rof Flower and Mr Lydekker, "no longer sufficient for the purpose [of a classification which shall embrace extinct forms], and some other method will have to be invented to show the complex relationships existing between different animal forms when viewed as a whole" Apparently the authors mein, by the last five words of this sentence, "when all are viewed together" The necessity for drawing up lists and catalogues in a linear series is deplored. but unhappily no attempt is made by the authors to grapple with the difficulty. A classification of the Mammalia in a linear series is given as far as families, and the names of groups containing only extinct forms are printed in special black type I should have been very glad to see some attempt to set forth in the form of genealogical trees the senior author's views on the genetic relationships of this confessedly artificial linear series I cannot admit that the division of the Mammalia into three groups-Prototheria, Metatheria, and Eutheria, or, as De Blainville called them, Ornithodelphia, Didelphia, and Monodelphia -- expresses a natural fact, if these three groups are regarded as equipollent, and as succeeding one another as three "grades" of evolution. It is not difficult to come nearer to an expression of actual genealogical relations than this lt appears preferable to divide the Mammalia primarily into two grades (A) the Monotrema, and (B) the Ditrema, only so do we give expression to the wide gap by which the archaic characteristics of the Monotremes separate them from all other Mammals. Then we can divide the Ditrema-not into two successive grades of structure -but into two diverging branches, viz Branch a Marsupialia, and Branch & Placentalia Of the Placentalia our authors say that their affinities with one another are so complex that it is impossible to arrange them serially with any regard to natural affinities. They might, however, it seems to me, embody their own conclusions in classificatory form, and divide the Placentalia into four diverging sub-branches, the chief being (a) the Typidentata, the three others being (b) the Edentata, (c) the Cetacea, and (d) the Sirenia The group which I call Typidentata our authors actually define, though they do not name it and use it as would surely be convenient. They say, "The remaining Eutherian Manimals [1 e Placentals after exclusion of Edentata, Cetacea, and Sirema] are clearly united by the characters of their teeth, being all heterodont and diphyodont with their dental system reducible to a common formula." I have for many years made use in my lectures of the classification of Mammalia above indicated which may be summarized thus :-

> Class MAMMALIA. Grade A MONOTREMA. Grade B DITREMA. Sub-bi ř š Š. ۵. Ą Polyprotod Typidentat

Sub-br. 6.

Diprotodonta

No doubt it is difficult, even with the use of the additional terms "grade," "branch," and "sub-branch," to set forth the relations to one another of the known orders and sub-orders of Typidentata: but the attempt must be made, and there are materials in the present work for gathering some indications of the form which such a tentative pedigree would take had the authors gone so far as to formulate it.

In the chapter on geographical distribution, the six zoological regions of the globe proposed by Dr Sciater in 1857 are accepted But here, as in regard to the treatment of morphological groups, it seems that a primary grouping of the divisions recognized might with advantage be introduced, which would give a truer expression of the historic relations of existing land surfaces than that adopted Reference is made to the proposed elevation of New Zealand into a primary region, but would not the truth be more nearly expressed by separating New Zealand and the rest of the world first of all, as Atheriogæa and Theriogaea? Should not the Australian region next be separated from the rest of Theriogæa? Theriogæa would then be divided into the Ferra Marsupiahum and the Terra Placentalium (without prejudice to the recognition of the occurrence of a limited number of Marsupials in the latter) The Terra Placentalium includes the five regions called by Sciater Palæarctic, Nearctic, Neotropical, Ethiopian, and Indian. The authors of the present work mention Dr Heilprin's opinion that the Palæarctic and Nearctic regions should be united and called the Holarctic region. But they do not adopt this opinion, nor refer to Huxley's proposal to term this same area Arctogæa, and his suggestive speculations as to the successive connections of the three great peninsulas (as they are at present)-the Neotropical, the Ethiopian, and the Indian-with this northern land surface

I have ventured to cite one or two instances in which the methods of classification adopted in the "Study of Mammalia" appear to be open to improvement I trust that I may without offence express a doubt as to what precisely is the meaning of the last part of the following passage :--

"The researches of palæontologists, founded upon NO. 1128, VOL. 44]

extinct forms, have shown that, in many natural groups of Mammals, if not in all, the brain has increased in size and also in complexity of surface foldings with the advance of time, indicating in this, as in so many other respects, a gradual progress from a lower to a higher type of development."

I confess that I do not understand what this "lower" and " higher type of development" refer to. The remarkable thing about the small brains of extinct Ungulata is that, whilst they differ enormously in relative size and in the low development of other features from the brains of living Ungulates, their possessors exhibited no corresponding difference of skeletal structure ; so that it appears that the brain has had an independent evolution. advancing in size and complexity from the initial phase of the primitive Ungulate far further than has the general body-structure. The gap in respect of brain between man and the highest ages, accompanied as it is by mere trivial differences of bodily structure, appears to be a less marked case of the same general phenomenon. We may say that the brain in the one case is in a lower and in the other in a higher stage of development; but whether the authors mean this merely, or that the whole animal has passed "from a lower to a higher type of development," and to what kind of morphological doctrine that phraseology belongs, are matters which do not immediately explain themselves.

The only way to write of so large, so comprehensive, and so authoritative a work as the present, is to point out a few matters for discussion which a rapid review of its pages suggests. Such indications of topics on which one would like to know more from the authors of a book of this kind are not fault-findings, but samples of the interest which it awakens in a sympathetic reader.

È RAY LANKESTER

FORTY YEARS IN A MOORLAND PARISH

Forty Years in a Moorland Parish By the Rev 1. C Atkinson, D.C.L. (London Macmillan and Co. 1801.)

"HE moorland parish of which Dr Atkinson writes is the parish of Danby, which lies among the Cleveland Hills, some miles inland from Whitby. Here he has worked as a clergyman for forty-five years. To a man of narrow sympathies and little intellectual curiosity the position might have been trying enough; but in the life of the people, in the aspects of Nature, and in local problems appealing to the antiquary and the historian, Dr. Atkinson has found sources of interest which have never lost their charm. In the present volume he records some reminiscences of the pursuits which have occupied him, and of the impressions which have been made upon him, during all these years, and a very fascinating record it is. He not only has powers of keen and accurate observation, but carries on his researches in a thoroughly scientific spirit; and he is a master of the difficult art of stating problems in a manner that secures attention while, they are being gradually solved. His immediate subject is Danby; but if the author bad never raised his eyes to look further afield, his readers might soon have felt that he had told them studies of casts of the interior of the cranial cavity of about as much as they wished to know. Facts relating to a particular locality can never be really understood unless they are brought into connection with kindred facts in other parts of the world. This is constantly borne in mind by Dr. Atkinson, and his ample learning enables him to apply the principle in many different ways; so that, when he is talking about Danby, he is often talking at the same time about wide regions of the British Islands, and even about stages of culture through which the greater part of the human race has passed

One of the most interesting of the sections into which the book is divided is the one headed "Antiquarian." In Danby, as in Cleveland generally, there are many prehistoric burnal-mounds, and a large number of these he has carefully excavated. The only traces of bronze he has discovered are " a few mouldering fragments of very thin plate, found with the unprotected bones of a cremated body, and not sufficient to fill a very small pill-box half an inch in diameter." Nevertheless, the contents of the larger "houes" prove conclusively that they belong to the Bronze Age, and Dr. Atkinson is of opinion that they date from the later part of the period. He has found many vases of the Bronze Age type, some jet beads, two polished axe-hammers, various bone pins, arrowheads and other objects of flint; and by far the larger proportion of these treasures may now be studied, along with similar treasures recovered elsewhere, in the British Museum Dr Atkinson tells with great spirit the story of the more memorable of his explorations; and he has much that is amusing to say about the wonder excited among his rustic neighbours by what seem to them his mysterious proceedings, and about the interest aroused in the minds of those whom he has from time to time induced to help him. Across the ridges between which he the dales of the district are ancient earthworks, all of which " are defensive against attack from the south, and in no other direction whatever." Of these dykes, which seem to be of the same period as the burial-mounds, Dr. Atkinson gives a full and lucid account, and he offers some suggestive hints as to their relation to other old fortifications in the neighbourhood He has also an excellent chapter on various pits which have often been described as the remains of "British settlements" There can be little doubt, as he shows, that in reality these pits are the remains of early mining excavations

Another valuable part of the book is devoted to folklore The belief in witches has not even yet wholly died out in Cleveland; and forty years ago it was still a more or less potent factor in the lives of the people. The author gives some curious instances of the power formerly attributed to witches, and of the means by which their devices were supposed to be thwarted by the "wise men" of the district. He suggests that witches may not always have been mere impostors, but that in some cases they may have been able to exercise the kind of influence to which the phenomena of hypnotism are beheved to be due. Even more interesting than the traces of faith in witchcraft are the survivals of "fairy," "dwarf," and "Hob" notions. According to a tale told to Dr. Atkinson by an old woman, there was a farm in Glaisdale where Hob, so long as he was not spied upon, did much excellent work at night. At last some one was curious enough to watch him, and it was thought he would be all the better for "something to hap hissel' wiv." Accord-

ingly a coarse shirt, with a belt or girdle to confine it round his middle, was made for him, and left in the barn where he worked. When he found the gift, Hob broke out in the following couplet.

"Gin Hob mun hae nowglit but a hardin' hamp, He'll coom nae mair, nowther to berry nor stamp."

Dr Atkinson was delighted with this couplet, for it preserves three words which had become obsolete forty years ago, and two of which-"berry" and "hamp"had no actual meaning to the speaker. "Stamp" was the word for "the action of knocking off the awns of the barley previously to threshing it, according to the old practice" "Berry," meaning to thresh, he had been "looking and inquiring for, for years, and looking and inquiring in vain" As to "hamp," he had "never had any reason to suppose that it had once been a constituent part of the current Cleveland folk-speech" The hamp was a kind of smock-frock, gathered in about the middle and falling below the knee, and was at one time the characteristic garment of the English peasant The word "seems to be clearly Old Danish in form and origin "

There are several chapters which will give pleasure to students of geology and ornithology, and in his notes on weddings, burnals, the harvest-home, and holy wells, the author displays much ingenuity in detecting survivals of what were in past times wide-spread customs. In the interpretation of old historical documents, and in the purely descriptive parts of the book, he is equally successful. Some readers, finding so many things to lure them on from the beginning of the work to the end, may be dissipated to the historical production of the work of the survival su

OUR BOOK SHELF.

Anatomy, Physiology, Morphology, and Development of the Blowsky (Calliphora crythrocephala) Part II By B. Thompson Lowne, F.R.C.S., F.L.S., &c. (London R. H. Porter, 1891)

This general features of this study in insect anatomy have already been noted (NA 1028, vol Mills, 27). Part II. describes the exoskeleton in considerable detail, and contents many useful and elaborate figures Plate v. and the accompanying explanations give the author's news upon the morphology of the mesc-thead. The pre-oral part he regards as developed from three bladder-like swellings, to which correspond three primary divisions of the cephalic nerve-centres. The post-oral part is supposed to arise by the fusion of three jaw-bearing segments. The terminal portion of the probosets as probably developed, according part of maxilia. The description of the mouth-parts is very full, and the figures are extremely wood.

The thoracic skeleton is also minutely described, perhaps over-minutely, seeing that, mour author's words, by a classification of the various sclentes indicative of their morphological significancies is not possible with our present knowledge. Other careful descriptions by special students show that it is easy to interpret the complex thoracic structures in a different way from that here adopted.

Excellent figures are given of the legs, feet, and wings,

and the description of the foot of the fly is of very special interest. The wing-joint is described with great care and thoroughness, in connection with the mechanics of

flight
Comparisons between insect and vertebrate structures are made with great boldness One example will probably astonish common-place morphologists observed that the femore-tibial part of the fiv's leg forms at first a mere lateral prominence, which is converted by segmentation and constriction into a bent knee, the upper part yielding the coxa and femur, the lower part the tibta. Mr. Lowne confirms this account, and illustrates it by figuring five stages (Fig. 34) Next he compares the lateral prominence to the exopodite of a biramous limb. Then he adopts Dr. Gaskell's suggestion that the limbs of an Arthropod may correspond to the visceral arches of a Vertebrate. In the following sentence we reach the chmax. "The double character of the embryonic appendages in the Crustacea, and in the maxillæ of insects, as well as in the thoracic limbs of the rudimentary fly-nymph, is certainly very suggestive of the double character of the pterygomaxillary arch, or even of the hyomandibular in vertebrates."

So much conscientious labour has been bestowed upon this treatise, and it is so useful to the student of insect anatomy, that it is a pity to see the text encumbered with discussions which, to avoid dogmatism, we will merely call extremely hazardous. Would it not be better to magnum opus free of doubtful matter?

When all deductions have been made, the book must

be counted a valuble addition to the literature of the

subject

Races and Peoples. Lectures on the Science of Ethno-graphy By Daniel G Brinton (New York N D. C. Hodges, 1890 Sold by Kegan Paul, Trench, Trubner, and Co)

THE lectures of which this book consists were delivered at the Academy of Natural Sciences, Philadelphia, early in 1890. They present a good general view of the lead-ing principles of ethnography, as these are understood by the author. He begins with a discussion of what he calls the physical and psychical elements of ethnography, next treats of the beginnings and subdivisions of races, then takes in order the divisions in which he arranges the various groups of mankind, and finally deals with problems relating to "acclimation," amalgamation, and the influence of civilization on savages, and offers some the innuence of civilization on savages, and offers some suggestions as to the destiny of races. The human species seems to him to include five races—the Eurafrican, the Austafrican, the American, and insular and littoral peoples. Each of these is subdivided into branches, stocks, and groups; and an effort is made to define the traits which, according to Dr Brinton, the members of each race have in common It is not always easy to understand the principle of his classification. The Eurafrican race, for instance, includes the following The Eurafrican race, for instance, includes the following groups: Libyans, Egyptians, East Africans, Arabans, Anyasanians, Chaldmans, Euskarians, Indo-Germanic or Celindic peoples, and peoples of the Caucasis These peoples are all white; and Dr. Britton thinks was peoples are all white; and Dr. Britton thinks was also say of them, "harr way, nose narrow." But the differences by which they are separated from one another trempts doubthful subcluse; was an experiency, dust it is not. tremely doubtful whether we are warranted in attributing to them a common origin, except in the wide sense in which a common origin is attributed to humanity generally. So long, however, as Dr. Brinton's classification is understood to be merely a convenient way of bringing together great masses of facts, it may be of considerable service to students. The book embodies the results of much careful research, and is written in a clear and vigorous style.

NO. 1128, VOL. 44]

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions ex-persed by his correspondents. Nather can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communication.]

Crystals of Platinum.

Since writing a note on this subject to Nature (vol. xiiii. p. 541) I have found that it is by no means requisite to use lopaz in order to obtain crystals of plannum from a ribbon of topar in order to obtain crystals of plantium from a riboto that that metal heated by a current. Thus the ribbon may be dusted over with quartz dust, and if the temperature be raised to that at which this is slowly melting (1430° C ahout), crystals of at writer that is slowly melting [1430° C about), crystals of plannum gaiher upon projecturing points on the quarts. Doubt-less the presence of fluorine will facilitate, as described in my former letter, the volalitation of the platinum, but there is little doubt that at a temperature some 300° below its melting-point (1730°; Y 1001e) there is a slow volalitation of the metal due either to heat pure and ample, or to this in conjunction with the presence of a current as in high vacua.

with the presence of a current as in high vacus.

To put the possibility of chemical action out of the question, I weighted a clean ribbon of pure platinum, g centimetres in length, and passed such a current through it, for 50 minutes, as raised it to nearly the melting-point of palladium (150°, Violle) from the melting-point of part (Afrye's tor Too' Feren s. Stockholm Forhands, Pal. 13, Halt 2, 1891) obtact crystals of paltamum formed by the action of chloring est upon plainamum formed by the action of chloring est upon plainamum formed the observations of the memberature. The figures illustrating has paged deposit crystals smaller to three obstance by the present of 100°.

Physical Laboratory, Trinity College, Duhlin,

Porpoises in the Victoria Nyanza,

In Dr Carl Peters's "New Light on Dark Africa," he speaks of "some large gray bellied porpoises tumbling about "in Lake Victoria Nyanza, "and rollicking in the tepid flood" (see p. 445). Yicioin a Yanna.

I should be glad to know whether there is any other animons, for the occurrence of a Cetacean in this lake. It is possible, but very improbable, as no Cetacean are known to occur in the Nile, or other African fresh waters, although there has been a report of the Manattee being found in the Shari, which runs into Lake Tohind (see Barth, "Ressen," ii p 280), and the Manattee Lake Tohind (see Barth, "Ressen," ii p 280), and the Manattee Tohind (see Barth, "Ressen," ii p 280).

The Zoological Station at Naples.

It is desirable that the names of any biologists who wish to make use of the British Association Table at the Naples Zoological Station, during the year commencing in September next, should be in the possession of the Committee before the meeting of the British Association at Cardiff

Intending applicants are therefore requested to send in their names, and a statement of the nature of the work they propose to undertake, before June 30, to me as Secretary to the Committee W. PERCY SLADEN 13 Hyde Park Gate, S. W., June 6,

A BRITISH INSTITUTE OF PREVENTIVE

ON Friday, June 5, Sir Michael Hicks-Beach received in one of the large rooms of the Victoria Hotel, on the ot the large rooms of the victoria riote, an unusually numerous and influential deputation on behalf of the British Institute of Preventive Medicine S. M. Michael Hicks-Beach was accompanied by Sir Henry Calcraft, K.C.B., Secretary to the Board of Trade, Mr. Courtenay Boyle, C.B., and Mr. Walter J. Howell.

Among the members of the deputation were the Duke of Westminster, the Earl of Feversham, Sir Frederick Abel. Sir F. Bramwell, Sir John Lubbock, Sir Benjamin Baker, Dr Farquharson, M.P., Sir William Thomson, Sır James Baın, Sır Joseph Fayrer, Sır Philip Magnus, Sır Jacob Wilson, Prof. Dewar, Sur Douglas Galton, Sır Acchibald Geite, Sır William Houldworth, M.P., Sır George Gunphy, Mr Haldame, O. C. Ray, Lankester, Prof. Norman Lockyer, Mr Blundell Maple, M.P., Sır Ceorge Gabrel Stokes, M.P., Sır George Gabrel Stokes, M.P., Sır George Gabrel Stokes, M.P., Sur George Gabrel Stokes, M.P., Port Mardon Sanderson, Sır Henry Tremma Wood, Prof Victor Horsley, Dr Armand Kuffer, Mr Prestiley, Grand Gabrel Stokes, M.P., Sur George Gabrel Stokes, M.P., Port Mardon Sanderson, Sır Henry Tremma Wood, Prof Victor Horsley, Dr Armand Kuffer, Mr Prestiley, Braynson, and other Scotches, the Royal, the Linnean, and other scientific Societies.

The following letters were read from Prof Tyndall and Prof Huxley .-" Hand Head, Haslemere, June 3, 1891.

"My DEAR SIR JOSEPH,—The battered remnant of four deadly assaults, I am still a prisoner in my bed Were I a free man, I should deem it a privilege to join your deputation to Sir Michael Hicks-Beach on June 5 I entirely sympathize with the movement

"Let me here record a small experience of my own "Let me here record a small experience of my own Last summer, while crossing from Dover to Calais on my way to the Alps, I noticed, huddled up in a corner of the steamer, a poor English boy He seemed loady and depressed, and I spoke to him "Where are you going, my boy? I asked 'To Paris,' was the reply 'And what are you going to do in Taris?' 'Well, sir, said he, 'I have been badly butten by a med dog,' and I am now on my way to Mr. Pasteur, who I hope will save

"The case prompted sad and bitter musings Here was wealthy England, with the amplest means at her disposal, with some of her ablest men ready to investigate and apply those some of her ablest med ready to investigate and apply those means, insansity forbidding such investigation, and compelling rescued from the most horrible of deaths. As I spoke to the did, the virtulent rable virus was probably already in his blood, and his chance of life depended on the promptness with which Pasteur's succeine could be introduced to compact and destroy that virus. Every hour lost in the collection of money for the boy's journey and in making arrangements with Pasteur for his reception-every hour lost in his transport from England to reception—every hour lost in his transport from England to France—was so much time given to the virulent virus to pursue its fatal work, and to ruin the chances of the boy's rescue This is the state of things to which we in England are forced to submit; this is the condition to which we are reduced, through the deference paid by English statesmen to a noisy and an ignorant

"But while the investigation and treatment of hydrophobia "But while the investigation and treatment of hydrophobas confer immoral honour on Pasteur, this malady is but a small item in the array of disorders now demanding investigation Suspected from time to time by men of geniss in the past, the fact that all communicable diseases are due to micro organisms, which increase and multiply after the manner of living things, has, in the opinion of our fair authorities, been now reduced to has, in the opinion of our next authorities, ocen now resuccess to demonstration. Vor proposed mixture is to be devoted to the investigation of such organisms—to the study, that is, of the science of bacteriology. In regard to questions of life and health, such an institution is the most pressing need of England at the present hour A good deal of the weary time which I have been forced to spend in bed during the last six months have been forced to spend in bed during the last six months. has been devoted to making myself acquainted with what is being done by the staff of the Hygienic Institute of Berlin, an institute of which the German auton may well be proud. I have occupied myself in drawing up an account of the receatly carried out in connection with the institute. In regard to our most fatal disorders, these researches will effect a revolutroon, not only in public knowledge, but also in the thoughts and practice of medical men It would, in my oplinon, be a lamentable mistake on the part of an English statesman to place himself in official antagonism to the eminent and illustrious men who on June 5 will advocate the founding of a similar institute in England

in England
"It is, I think, fortunate that you have in Sir Michael HicksBeach a stateman not likely to fall into the extravagances of
senumentalism. The overwhelming preponderance of English
intellect will be represented by the deputation. "Me may rest
saured of it that this preponderance will become more and more

conspicuous, until finally the misguided opponents of a true philanthropy will cease to engage the attention, much less enlist the sympathy, of the English people "Belleve me, dear Sir Joseph, most faithfully yours,

"JOHN TYNDALL

"Sir Joseph Lister, Bart.

" Hodeslea, Eastbourne, June 2, 1891 "DEAR SIR JOSEPH LISTER .- I am very sorry that I am

"DEAR SIN [OSEPH LISTER,—I am very sorry that I am unable to join your deputation on June 5.
"If I outld have been with you, I think I should have asked to be permitted to point out to the Frendent of the Board of I raide that medical science is not excepted from the rule which holis good for other branches of natural knowledge, and that it can be advanced only by reasoning based upon observation acquement, and constantly convolided by both, especially by the experiment, and constantly convolided by both, especially by the

"Further, that by working in this fashion a marvellous improvement of medical science has been effected during the last half-century, and that the harvest of what Bacon called 'fruits,' which is now waiting for the gatherer, might fully occupy half a dozen such institutes as that in which we are

interested.

"Starting from the unquestionable facts that the work we propose to undertake is of supreme public utility, and that the number and extent of the problems of pathology are enormously number and extent of the provients of partology are enormously great in proportion to any existing means of dealing with them, I should have ventured to ask why we should be refused the only privilege we seek—namely, that official recognition by the Board of Irade which will afford the institute security against

the possible misuse of its funds in future?
"No doubt, however, all these points will be much more effectually put by yourself and other members of the deputation. "I am yours very faithfully,

"Sir Joseph Lister, Bart , F R S."

Sir Henry Roscoe, M P, in introducing the deputation, said that it represented not only the whole body of medical men in this country, but also, without exception, all the scientific elements amongst scientific men, and also a large number of others who were interested from the national point of view in the establishment of an institute of preventive medicine for this country, and for which it was proposed to obtain incorpora-tion under the Board of Trade He need not go into the ques-tion as to the national importance of an institution of this kind There was no civilized country in Europe, and scarcely anywhere else, in which this subject had not awakeaed the interest where ease, in which the abolect had not awakeed the interest and claimed the attention, not only of the scientific men, but also to a great extent of the Governments of those countries What they asked was that Sr Michael Hicks-Beach would be good enough to enable them to found and to carry on a British Institute of Preventive Medicine, analogous and of a similar Institute of Preventive Medicine, anatogous and of France, Germany, form to those great institutes which existed in France, Germany, They were form to those great institutes which existed in France, Germany, Rissua, and in a great aumber of other countries. They were sorry to find that the object which they had in view and 'b. request that they made to Sir Michael had not met altogether with the success which they had hoped. They learnt from the answer which he had given to Major Rasch in the House of Commons that the erfensal to grant what they requested was based on objections received by the Board of Trade. They merely asked that the institution should be registered under the Limited Company Act, with the omission of the word "limited," Limited Company Act, with the omission of the word "limited," an order to imprise the public with the fact that the institute was not established for the purpose of gain, but jurily for the fact that a part of the a rok would include experiments on animals. In reply to this they had the opinion of counsel that the Board of Trade had only to satisfy themselves that the object was charatable, and that the promoters were persons whose positions was a sufficient guarantee of the high character

of the proposed institute
Sir Joseph Lister said the niject of their deputation was to request Sir Michael Hicks-Beach to reconsider his decision, and request. Sir Michael Hicks-Beach to reconsider his decision, and to grant the lonce under the Board of Trade which was really, as a woold seem, almost essential to the property; if not indeed to the very ensattee, of the institute It was essential, in order that they night hold money in trust, that they should be incorporated. They had been promised a large sum of money, the receipt of which would be essentially dependent upon their incorporated as in dirthey were moreoprosted as a limited inhabity. company they would not be able to appeal to the public for funds with any success. In the first place, their institution would have a mercantile character, which would tend to repel sub-scribers; and they had the opinion of counsel that under such scribers; and they had the opinion of counsel that under such circumstances it would be in the power of the subcribers at any time to agree to have the natitute wound up and the funds divided amongsit themselves To appeal to the public for sub-scriptions, therefore, under these conditions would be absolutely hopeless. On the other hand, if he licence were granted there could be inserted by the Board of Trade a condition that the funds of the institute should be used only for scenatic and charitable objects, and in that way their position would be per-fectly secured. The only practical alternative, if it was still thought right to refuse their request, would be that they should be incorporated by Act of Pariament—a process which would involve very great loss of time and also very serious expense The importance of the object which they had at heart was one The unportance of the object which hey had at heart was one which he thought need hardly he much dwelt upon Pereentive medicine based upon bacteriology was a matter of comparative and every year and almost every week they were learning of new trumphs schleved in the discovery of the essential nature of discase and of the means of preventing such disease. He might be permitted pathaps to refer to one or two illustrations of the swate of the work carried on at such institutes both to man and to the lower animals The work such institutes but to manage to the loves animals and dogs done by M. Pasteur for the tescue of those bitten by mad dogs from the horrible death of rahies was bearing invaluable fruits It had been estimated that within four years at the Pasteur Institute 12,000 lives had been saved During the last six years Institute 12,000 ween and neen saved During the last my years 403 British subjects had been treated, and out of those 403 only seven had died. If they took into account the loss of time in-volved in making arrangements for going to Paris, and con-sidered also that the eyer or of M. Pasieur's treatment was to intercept the disease before it arrived a the vital organisms in the brain, they might anticipate a large amount of success if they had the means in this c unity of having the same treatment had the means in this c usity of having the same treatment carried out. From Germany had come the discovery of what was termed tubercle bacillus—that was to say, the micro-organ-ism which was the executal cause of tubercle, the greatest physical sourge that afflicted the human race. To establish that physical scourge that afficied the human race. To establish that that bacilius was really the essential cause of this disease in all its diverse forms required a large air uni of investigation such as could only be carried on in institutes like that which they desired to see established. That the institute would be of great benefit also with regard to disease of the lower animals might be seen from the discoveries made as to the cure of anthrax by M from the discoveries made as to the cure of antarax my m Pasteur, and as to the treatment of another affliction. Known as "quarter evil" by a scientist of Lyons Various bacteriological aboratories had been alreadly established in the British Islands, but it was universally allowed that none of those existing was in the least equal to a great institute such as they desired to see established. One proof that such was the case were researched. established One proof that such was the case was presented by continually to Paris or to Berlin for the superior selvantages continually to Paris or to Berlin for the superior advantages that they could obtain there. He ventured to think that the mass of educated opinion represented by the deputation was surely more deserving of attention than the views of those who, with whatever excellent intentions, had petitioned against their scheme. The truth was that objections, were made because the scheme. The truit was that objections were made because the petitioners objected alticyclient to the performance of experiments upon living animals, and not because they thought that there was already sufficient opportunity for work of this kind. If those petitioners knew how very small was the amount of suffering really tioners knew how very small was inc amount or supering really inflicted upon the animals in such an institute, and how scrupu-lous was the care taken to avoid all needles- pain, they would not (at least, the great majority of them would not) have made the opposition that they had made. He even doubted whether the opposition of their being likely to perform experiments upon living animals was one which the Board of Trade had any fair reason to occupy itself with. The licensing of places for the performance of such experiments, and the heening of individual experimenters had always rested with the Home Secretary.
Foreign institutions such as that which they desired to see established had been largely endowed by the Siste, and he did not relinquish the hope that our Government might at some future time see its way to give them substantial aid. But, however that might be, they ventured to hope that no department of this Government would oppose any unnecessary obtacle to an enterprise which had for its sole object the welfare of humanity, the

health of mankind and the lower animals, and the general

progress of the public weal.

Sir Lyon Playfair, M.P., said that experiments on living animals had been sanctioned by Parliament, which had intrusted animals had been sanctoned by Farliament, which had intrusted the Home Securitary to make unlitable restrictions for the carry-moted differently from those in foreign countries, which were being founded by the Sites, and the deputation only saked to be allowed to associate for a purpose recognized by Parliament, and with such restrictions as Sir Michael Hicks-Beach or the

and with such restrictions as Sir Michael Hicks-Beach of the Home Secretary though proper to Impose Prof. Dewar spoke of the importance of the proposed institute from a chemical point of view, and Dr. Ray Lankester and Sir James Cnehton Browne also spoke.

Sir M Hicks-Beach, in reply, said:—I hope that it is not through any fault of mine that those who have arranged for this through any fault of mine that those who have arranged for this deputation have not come to me in the ordinary numbers of a summarised of the control of the present had come to me saying what has been said to-day, and authorized to speak on behalf of all of you, I can assure you that authorized to speak on benair of all of you, I can assure you that I should have attached as much weight to their arguments as I can do now But, of course, I accept your presence here as a strong testimony to the great interest that you feel in this subject I am sorry to confers to have differed from so many ject I am sorry to confess to have differed from so many gentlemen of such enuments as those who have supported this novement, and to have found myself unable to grant the appli-mission to tegister the Association without the siddition of the word "limited". It is only due to you that I should explain, as shortly as I can the reasons which induce me to arrive at that decision. Now, the section of the Act of 1857, under which you are five to set, lays down two preliminary requirements which must be proved to the satisfaction of the Board of Trade—first, that the Association shall be formed for one of several purposes, such as, for instance, that of promoting science, or some other useful object, secondly, that the profits or income or some other useful object. A secondly, that the promis or income will be applied to promote the objects of the Association, and that the payment of dividends will be prohibited. Now, I will assume that you have complict with both these requirements. I say nothing to the contrary. But the proof of such compliance does not, in my opinion, compel the Board of Trade to act on the section. Something has been said to day to the effect that you have obtained counsel's opinion that it does compel the Board of Trade so to act. I have taken another view—I admit without legal advice If you will place before me the opinion upon which your view is based, of course I shall very carefully consider it, and myself obtain legal advice upon that point, consider it, and myself obtain legal store upon that point, because I rew it as an important point, as you will see from what I am going to say. I have considered, as I said, that the section of the Act only empowers the Board of Trade to act, and leaves it to the Board of Trade to decide whether the conditions or explaintons should be imposed and inserted in the memorandum and articles of association. It therefore seems to me that the Board of Trade could hardly grant used a licence without expressing approval, by the mere last of the grant, of the Association to which it is granted. In your case I think I have been considered that the property of the property interpret Unisse 30 of your memorandum, I understands—Ann I also gathered from what has been said to-day—"that experiments on living animals calculated to give pain," to quote the words of the Act of Parlaments, are included among your objects; in one word, that vvinection would be part of your works. Now, this is a subject which the Legislature by the Cruelty to Animals Act, 1876, has placed under the control, not of the Board of Trade, but of the Home Office. By that Act, as you know, vissection is made illegal except by licence from the Home Office, and under the most stringest regulations, including Inspection by inspectors of the Home Office. I assume that when you had established this institution, supposing my locance were granted, an application would be made to the

Home Office for a licence or licences for wivection on the premue of the institute for some one or more of its members. It seems to me that the Home Secretary would have fair ground composition and an account of the composition of the compos

been expressed I shall be glad to receive.

Sir John Lebbock, in moving a vote of thanks to Sir Michael Hicka-Beach, said has Sir Henry Roscoe had authorneen him of the state of Trade. Virturection was after all a very small part of the question before them, unless, indeed, virusction was to be understood as applying to the indeed, the state of the state

The President—I ought to mention that any of the precedents which have been mentioned I should like to have placed before me.

The deputation then withdrew.

EARTH-CURRENTS AND THE ELECTRIC RAILWAY

A WELL-MAKED case of interference with the earth-currents recorded at the Royal Observatory, Greenwich, due apparently to the working of the new Electric Railway, having recent prove to esperienced, of which some account might prove to electricians, the Astronomer-Royal has kindly allowed me to communicate for publication in Natural some particulars in regard thereto.

It is known that for many pears past a continuous photographic register of earth current has been maintained at the Royal Observatory There are verticated for one circuit the earth-plates are at Angerstein Wharf (A. W.), on the southern bank of the River Thames, near to Charlton, and at Lady. Well, Lewisham (I. W.); for the other circuit the earth-plates are on Blackheath (B.) at the south end of the North Kent Railway tunnel, and at the North Kent Railway tunnel, and the North Kent Railway tunnel on of the North Kent and Greenwich lines. The earth connection is in each and Greenwich lines. The earth connection is in each acts made by an undependent cropper plate; these plates

are used only for the earth-current lines, no other wires being attached thereto. From the AW earth-plate the wire passes by the South-Eastern Railway lines to the Greenwich Station, thence underground to the Royal Observatory recording apparatus, returning underground to the Greenwich Station, and thence by the railway to the earth-plate at L. W. Similarly for the Blackheath-between the L. W. Similarly for the Blackheath-between the AW and I. W. earth-plates at 3, miles, and between the B and N. K. E. earth-plates about 24 miles. The azimuth of the AW—L. W. line, reckoning from magnetic north towards east, is 50°; the azimuth of the AW—L. W. line, reckoning from magnetic north towards west, is 46°. Registration is effected in the usual way. In which carries a small mirror, on this the light from a fixed gas-lamp falls, and, reflected therefron, finally reaches the revolving cylinder as a small mirror, on this the light from a fixed gas-lamp falls, and, reflected therefron, finally reaches the revolving cylinder as a small grot of light

Some few particular's concerning earth-current motions generally may perhaps be given It has been found that all cases of disturbance of the magnets are according to the control of the control of the magnets ever accura without corresponding active earth-currents, as may be seen by the plates (copies of the various registers) given in the several Greenwich volumes since the year 18's. On days on which the ordinary disturbed change, earth-currents are very feeble

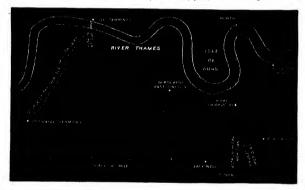

may devote a few words to the description of a previous case in which the interference was much less marked in any devote a few words to the description of a previous case in which the interference was much less marked in character, although, with some intermissions, otherwise very persistent. Some five years or more ago it was remarked, in the AW – LW register, that at one part of the day a slight dislocation of the trace occurred, in no case midicating a change of potential of more than or taken middle of the control of the

We now come to the recent much more serious case of interference. Towards the end of last year anomalous appearances began to be observed in both of the earthcurrent registers, not continuously but in a somewhat irregular manner Now, however, for some months past, these new interruptions have settled down into a regular order What is perceived is that the interference in question, causing a continuous vibration of the registering needles, commences shortly before 7h in the morning, goes on all through the day, terminating shortly after 1 th, goes on an universal months on in the evening. This went on for several months on week-days only, ceasing on Sundays, nothing being seen after 11h p.m. on Saturday, until 7h am on Monday, But on Sunday, April 5, and on every succeeding Sunday. But on Sunday, April 5, and on every succeeding Sunday. to the present time, the interference has been experienced also on a portion of the Sunday, commencing at about 1h pm, and terminating usually at 10h pm. or shortly afterwards. Various experiments were made with the view of discovering the cause of these anomalous appearances, but without definite result. Quite recently, Mr Leonard, the telegraphic superintendent of the South-Eastern Railway, to whom the Observatory is much indebted for considerable assistance in many matters connected with the earth-current work, was led to suggest

that the exceptional appearances were most probably due to the influence of the new Electric Railway. three miles in length, and having terminal stations in the City and at Stockwell. A comparison being made be-tween the observed times of interference with the earthcurrent registers, and the published times of running of the Electric Railway trains, it was found that these were simultaneous Further, in the early part of the year, during the period in which the earth-current registers were free from interference on Sunday, there were correspondingly no Sunday trains But on Sunday, April 5, it appears that trains commenced to run on Sunday afternoon, the same day that Sunday inter-

The line of the Electric Railway runs from about north-east to south-west magnetic, or more accurately norm-east to south-west magnetic, of more accurately the azimuth of the line, reckoning from magnetic north towards east, is about 50°. The nearest earth-plate to the railway is the N.K.E.J plate, which is distant from the railway, in a perpendicular direction from it, about 2½ miles

The correspondence so far as the comparison goes is complete During the periods of interference the registering needles at the Observatory are in continual vibration.
Whether the impulses are in one direction only or in both directions, and what is their frequency, cannot be readily determined from the registers Eye observation of the ference was first noticed at Greenwich, and these Sunday needles may perhaps reveal something to us on these

afternoon trains have been since continued. The whole matter is better seen in the annexed tabular statement .-Times of interference with earth current registers at the Royal Observatory, Greenwich Train service on Electric Railway On week days On week days. City

OBSERVATORY. THE Report presented by the Astronomer-Royal this year is of more than usual interest. The first part deals with proposed new buildings.

It has been decided that the museum or storehouse for NO. 1128, VOL. 44]

points. The abnormal excursions of the needles indicate a change of potential varying from a small fraction of a wolt to perhaps the one-third of a volt or more When any marked earth-current action arises, the interference becomes in some degree neutralized, and less marked in character

It was found in the course of previous experiments, that when, instead of employing the complete AW-LW. circuit, the A.W branch only was allowed to register, by circuit, the Arv orante only was anowed to register, by putting the wire to earth at Greenwich, the amplitude of vibration of the needle was not perceptibly changed, neither was it changed when the LW branch only was allowed to register Gorrespondingly, when the B branch alone of the B-N K E.J. circuit was allowed to register, the vibration was much diminished, whist with the N K.E.J. branch alone registering it was much increased
William Ellis.

portable instruments and apparatus should be built so as portaine instruments and apparatus should be built so as to form the central octagon of a future cruciform struc-ture in the South Ground, which would accommodate the physical branch of the Observatory, and would carry the Lassell equatorial and dome at such a height above the ground that the neighbouring trees would not interfere with the effective use of the instrument. The building for the Museum was commenced at the beginning of March. In consequence of a recent decision of the Admiralty to largely increase the number of chronometers and deck watches for the Navy, additional accommodation for chronometers is required immediately, the space in the present chronometer room being

diately, the space in the present chronometer room being insufficient even for existing requirements.

In other directions the difficulty of providing in the existing Observatory buildings for the accommodation of the increasing staff and of the accumulating material is severely felt, and it is very desirable that the pressure on the space available should now be relieved by means of a comprehensive scheme, which would supply a suitable fireproof brick building to replace the wooden sheds and huts which now disfigure the Observatory grounds, and to provide for the expansion which has taken place in late

to provide for the expansion which has taken place in late years, and which may be expected to continue in the future. To provide for the efficient working of the 28 men refractor about to be mounted on the south-east equatorial, the Admirally have authorized the construction of a new iron-framed dome, 36 feet in diameter, to be erected on the south-east tower in place of the existing wooden drum, which, as mentioned in the last Report, has been so much strained in the course of thirty years, that there is great difficulty in turning it sattempt was made to render the existing dome more serviceable by bolting the framework together more thoroughly, and by substituting properly turned spheres for the cannon-balls, but though the dome is not now liable to strick fast as formerly, it is still very difficult to turn, and cannot be considered serviceable. The new 36-foot dome, which is being constructed by Messrs. T Cooke and Sons, is of peculiar form, adapted to the conditions of the case, the diameter being greater than that of the tower on which it is erected.

A photographic telescope with 9 inch object glass by Grubb, and a prism of 9 inches diameter by Hilger, have been generously presented to the Royal Observatory by been generously presented to the Koyal Observatory or Sr Henry Thompson The telescope has been mounted on the Lassell telescope as a photoheliograph, to give sinch pictures of the sun, a carner awith Dallmeyer doublet (from photoheliograph No 4), and an exposing shutter, specially designed to give very short exposures, being attached to it

Six more electric hand lamps and an Ampère gauge (Sir W Thomson's) have been purchased

In view of the advantage resulting from the use of electric lighting for the photographic equatorial and for other instruments, the Astronomer-Royal considers it very desirable that an electric light installation should be provided for the Observatory, so that this method of lighting, which is specially adapted to the requirements of an observatory, may be applied to the instruments generally. The system now in use of charging storage cells from primary batteries, is necessarily extravagant, and it does not admit of the desired extension

With regard to the work done, the following statement shows the number of observations made with the transit-

circle in the year ending May 10, 1891 .-

Transits, the separate limbs being counted as separate observations
Determinations of collimation error 6036 307 Determinations of level error 390 5789 Circle observations
Determinations of nadir point (included in the number of circle observations Reflection observations of stars (similarly included)

For determining the variation of personal equation with the magnitude of the star, 324 transits, not included in the above, have been observed. The apparent magnitudes of the stars are altered by placing a wire gauze screen in front of the object-glass of the telescope, and part of a transit is observed with clear aperture, part with obscured. The comparison of the two results gives

NO. 1128, VOL. 447

the difference of personal equation for a definite change of magnitude. It appears that all the four regular ob-servers record the times of faint stars later than bright,

the difference per magnitude being about o' ois Altazimuth - The total number of observations made in the year ending May 10, 1801, is as follows

Azimuths of the moon and star	5		253
Azımutha of Mark I			123
Azimuths of Mark II			193
Zenuh distances of the moon			118
Zenuh distances of Mark 1			124
Zenlth distances of Mark II			188

Reflex Zenith Tube -Since the date of the last Report, 14 double observations of y Draconis have been made and completely reduced to the end of 1800 M Lowy's recent work seems to show that the determination of the constant of aberration with this instrument is more trustworthy than had been supposed, though the circumstance that the observations give a negative parallax for y Draconis suggests that there is some unexplained source of error

Sir H Grubb reports that the object-glass and tube of the 28-inch refractor are now practically ready for mounting; but the Astronomer-Royal proposes to delay this operation until the completion of the new dome on the south-east tower mentioned in the first section of this Report

Work with the 13-inch photographic refractor was seriously delayed by the accident to the driving-clock, andr later, by the illness of Mr. Criswick, but 81 stellar photographs have been taken, all of which must be re-garded as more or less experimental Ferrous oxalate garacu as more or less experimental. Ferrous ovalate development was used throughout, and all the plates were photographically impressed with the reveau kindly supplied by Prof. Vogel. The exposures have varied from a few seconds to about an hour; and trails have been a few seconds to about an nour; and trains have occur taken both on the equator and near the pole to test the adjustment for orientation Several different kinds of plates have been used, including Cramer, Seed, Paget, Star, Mawson and Swan, and Ilford; and on the whole the choice seems to lie between the Star and the Ilford plates

Spectroscopic and Photographic Observations - For determination of motions of approach or recession of stars, 286 measures have been made of the displacement of the F line in the spectra of 31 stars, and 14 of the δ line in the spectra of 6 stars, besides comparisons with the spectra of Mars, the moon, the sun, or the sky, as a check on the general accuracy of the results. The series of observations with the 123-inch refractor is now practically completed, and the results are under discussion An examination of those for the 21 stars most frequently observed shows that there is a systematic error depending on the hour angle, thus necessitating a correction for the position of the spectroscope at the observation

In the year ending May 10, 1891, photographs of the sun have been taken at Greenwich on 224 days, and of these, 483 have been selected for preservation, besides 18 photographs with double images of the sun for determination of zero of position

Magnetic Observations - The following are the principal results for the magnetic elements for 1800 -

17° 28'6 W 3 9546 (in British units). 1 8234 (in metric units) Mean horizontal force (67 21 19 (by 9 inch needles) 67 22 53 (by 6-inch needles) 67 24 24 (by 3-inch needles) Mean dip

Mean declination

Meteorological Observations .- The continuous registration of meteorological phenomena has been maintained without interruption, except for four days in February when the old thermograph and shed in the magnetic ground were dismounted, and the new thermograph and shed were transferred from the South Ground to the position formerly occupied by the old instrument, to make way for the new buildings in the South Ground

The mean temperature of the year 1890 was 48°6, being 0°6 below the average of the preceding 49 years. The highest air temperature in the shade was 82°8 on August 5, and the lowest 13°1 on March 4 This latter is the lowest temperature registered in March since 1841. being the same us that recorded on March 13, 1845. The mean monthly temperature in 1890 was below the average in all months excepting January, March, May, and Sept-ember In December it was below the average by 10°0, and in January above by 5° 2

The mean daily motion of the air in 1890 was 272 miles, being 10 miles below the average of the preceding 23 years The greatest daily motion was 837 miles on January 26, and the least 32 miles on August 6 The greatest pressure registered was 14 5 pounds on the

square foot on January 26.

During the year 1890 Osler's anemometer showed an excess of about three revolutions of the vane in the

excess of about three revolutions of the vane in the positive direction N, E., S, W, N, excluding the turnings which are evidently accidental The number of hours of bright sunshine recorded during 1890 by the Campbell-Stokes sunshine instrument was 1255, which is about 35 hours below the average of was 1255, which is about 35 hours below the average or the preceding 13 years, after making allowance for difference of the indications with the Campbell and Campbell-Stokes instruments respectively. The aggre-gate number of hours during which the sun was above the horizon was 4454, so that the mean proportion of sunshine for the year was 0'282, constant sunshine being

represented by 1

represented by 1
The rainfall in 1890 was 21 9 inches, being 27 inches below the average of the preceding 49 years.
The winter of 1890-91 was remarkable for a long period of exceptionally cold weather which commenced on November 25, 1890. From this day till January 22

the mean temperature on every day except January 13 was below the average The temperature was conwas below the average was below the average. The temperature was con-tinuously below 32° on November 27, 28, December 10 to 19, 22, 23, 25, 28 to 30, January 2, 6 to 8, 10, 11, 17 to 19. The greatest defects from the average of 20 years were on November 28 (-19° 1), December 22 (-20° 7), and January 10 (-19° 3). The lowest temperatures 7e, and January 10 (-19° 3). corded during the three months were 18° 3 on November 28, 13° 4 on December 22, and 12° 0 on January 10 The mean temperature of December 1890 was 29° 8, or 10° 0 below the average of the preceding 49 years, the coldest December on record since 1841 previous to 1890 being that of 1879, whose mean temperature was 32' 4 In this same month. December 1800, only 2"4 of sunshine were recorded.

Chronometers, Time Signals, and Longitude Operations -- The number of chronometers and deck watches now being tested at the Observatory is 169 (113 box chronometers, 20 pocket chronometers, and 36 deck watches). The annual competitive trial of chronometers commences on July 4, and the trial of deck watches on October 24.

The time-balls at Greenwich, Deal, and Devonport are next referred to.

The reductions for the longitude Paris-Greenwich are now completed and ready for publication In reference to the discrepancy between the results of the French and English observers, mentioned in the last Report, Commandant Defforges visited Greenwich in June 1890, and went carefully through the reductions with Mr Turner and Mr. Lewis No mistake was found in the work, but several questions of some importance were raised. The results of the discussion and of subsequent correspond-ence are summed up in two papers by Mr Turner and one by Colonel Bassot and Commandant Defforges in the Monthly Notices of the Royal Astronomical Society, vol. li. pp 155, 407, and 413 respectively. As the matter of longitude between the Greenwich transit-circle and Cassin's meridian is 9m 20 86, while the French result Cassin's merician is 9" 20 so, while the French result (not yet published) is about 0"15 greater, a discordance which, though only about half of that found in the preliminary discussion, is still so large, that there seems to be no alternative but to repeat the work with special precau-

no alternative but to repeat the work will appecial precuations suggested by the experience gained.

The proposal to determine the longitude of Montreal as the base station for the Goodetic Survey having been sanctioned by the Admirally last December, arrangements have been made in concert with Frof. McLood, of the McGill College Observatory, Montreal, for a determination of the longitudes Montreal-Canso-Waterville-Greenwich, the termini of the cable, Canso and Waterville, being occupied as longitude and not merely as transmitting stations, a course which seems advisable in view of the great geodetic importance of these points The necessary funds have been voted, and the Com-mercial Cable Company have generously granted the use of their cable

The determination of the longitude of Washington has

been deferred for the present

During the past year, Lieutenants Heming, Monro, and Smyth, R.N., and Captain Haynes, R.E., have at various times been instructed in transit-observing. Mr S Hirayama, of the Tokio Observatory, was at work for some weeks studying the general organization of the Observatory

THE CLASSIFICATION OF THE TUNICATA IN RELATION TO EVOLUTION.

THE detailed classification of the Tunicata, and especially of the so-called "Compound Ascidians," has usually been found a matter of special difficulty by systematists, and each successive investigator has discovered grounds for modifying in important respects the grouping of genera and families established by his predecessors. A glance at the systems of Giard, Della Valle, von Drasche, and Lahille, all of recent date (re. post-Dar-winian, and since the introduction of modern methods and the recognition of the Tunicata as Chordata), shows the notable want of agreement between competent au-thorities. There is probably a special reason for this exceptional diversity of opinion, and I believe the cause is to be found in the course of evolution or phylogeny of the group, and especially in the complex relations be-tween the Compound forms and the other Tunicata.

In fact, if the matter be regarded from the point of view of the consistent evolutionist, the special difficulties vanish, the complicated relationships between groups vanish, the complicated relationships between groups (which can only be represented by dendritte diagrams, or even in some cases by networks) become explicable and natural, the great diversity in value of the assemblages of forms known as "genera" and "species" is simply what would be evpected, and the differences between the various classificatory systems (allowing for a few errors which have been corrected by later investigations) can be accounted for, and the conflicting opinions of the authors reconciled. But, on the other hand, if the subject be approached from the standpoint of the pure systematist, whose object is to divide and subdivide into clearly defined groups of approximately equal value, and to recognize only "good" genera and species, nothing but confusion results, it becomes practically impossible to distinguish and arrange naturally the groups of Simple and Compound Ascidians; and some of the most interesting and instructive points, such as the gradation of varieties into species and species into genera, and the individual variations in specific characters, are altogether lost sight of

These views were expressed partly in my Reports

on the Challenger Tunicata, but further work sincemosome very extensive collections from Australian seas
and on the Ascidians of our own coasts—has convinced
me that the only rational explanation of the protean
forms and labyrinthine intervelations of the protean
forms and labyrinthine species, genera, &c, have
not yet become markedly differentiated by the elimination
of intermediate forms, and where the animals are so much
at the mercy of their environment that a special presurge specific franzieres which are not useful), and where,
consequently, the relations between modification of structure and conditions of existence brought about by the
action of natural selection are exceptionally evident
of expects, and probably others with which I am not
concerned at present, can be, I think, satisfactorily explained. (1) the connection of the Simple with the
Compound Ascidians, and the classification of the latter,
(2) the value of some modifications of the branchial are,
(3) the numerous "species" of the genus Hestyrlius.

(1) If the attempt is made (as in most classifications) to regard the Compound Ascidians as a group distinct from the Ascidiæ Simplices, and forming either a parallel or a divergent line in regard to the latter, one meets at once with the serious difficulty that the Compound Ascidians show affinities with the Simple at several distinct points Three investigators approaching the Compound Ascidians after the previous study of certain Simple Ascidians -- say, the first fresh from Ciona, Esternascidia, and Clavelina, the second from Perophora, and the third from Myela and Polycus pa-could each make out a good case for the view that his new subjects were most closely connected with the genera he had just been working at could demonstrate the undoubted relations, in external form and in structure of branchial sac, between Clavelina and Chondrostachys, Colella and the other Distomidie, the second might point to the similarity (on which I personally lav no stress) of Perophora and the Botryllidae, in the relations of alimentary canal to branchial sac; and the third could show the close similarity between the Styeling and the Compound forms Synstyela, Goodsiria, and Choracocornus in nearly every detail of internal structure and all three would be partly right, and therefore unlikely to agree upon any one system of classification

But when the attempt is made seriously to form a conception of the past history or evolution of the forms in question, it becomes obvious that the Compound Ascidians are not a natural, but an artificial group That is, they are not the whole surviving descendants of a single group of ancestors, but are polyphyletic in origin, being derived from several distinct lines of ancestry which have arisen independently from different kinds of Simple Ascidians, and have since acquired the common characteristic of being able to re produce by gemmation so as to form compact colonies in which the members (ascidiozooids) are embedded in a common test or investing mass We know with as much certainty as we know anything in such phylogenetic inquiries that the ancestral Tunicates were not colonies, and that reproduction by gemmation was not a primitive character. This property has, then, been acquired secondarily by some ancestral Simple Ascidians, and may very possibly have been acquired more than once (though this is not at all necessary for my theory of the poly-phyletic origin). It follows from this view (which I have expressed before, but now feel more certain of from recent work), that if we are to retain the group Ascidiæ Compositie, or Synascidiæ, in our system, we must represent it as linked on to the Ascidiæ Simplices, at three points at least, and we must not attempt to arrange the families and genera in a series diverging from any one of these points alone, or if we do, we need not be surprised when we arrive at obviously unnatural arrangements which are in conflict with the classifications of our fellow-workers

On the other hand, we might abolish the group Ascidiæ Compositæ altogether as a sub-order of Ascidiacæ, on the ground that it is not a natural group (i e a compact set of descendants from a common ancestor—a single branch of

the genealogical tree)

But if we adopt this course with the Compound Ascidians. the same argument might be used in connection with other polyphyletic groups throughout the animal kingdom. They should all be broken up, it might be urged, as being artificial assemblages. And that would be a perfectly logical and definite position to take up, and one for which a good deal could be said, but before adopting it roologists should remember that it involves a loss as well as a gain If it gives "the system" a certain precision, and an advance of a step or two towards the goal of a completely natural classification, it at the same time destroys the recognition of characteristics which certain forms possess in common In whatever manner they have been obtained, there is no doubt that Compound Ascidians of the present day possess certain features by which they can be identified as Compound Ascidians, and this fact is surely worthy of recognition in our "system, My own opinion, then, is that the group Ascidic Com-posite should still be retained, but that its polyphyletic origin and multiple connection with the Ascidia Simplices should be carefully borne in mind when drawing

up any scheme of classification, or discussing affinities
(2) Some of the ideas noted above, and others to be discussed below, took definite form lately in reading a re-cently published memoir by M Fernand Lahille, in which, while giving a number of important original observations on the anatomy and bionomics of the Ascidians (and especially of the Compound forms) of the French coasts, the author introduces what I cannot help thinking in some respects an unfortunate attempt to remodel the classification of the Tunicata on lines which he communicated a few years ago to the French Association (Congrès de Loulouse, 1887), and now elaborates in detail. He regards the branchial sac as the most important organ in the Tunicata, and so it is in some respects, but that is not sufficient reason for regarding its modifications in structure as the sole characteristics of the primary groups For example, the Appendicularians, instead of being called Larvacea or Copelata, and characterized by the presence of a tail containing the urochord, are placed in a group "Atremata," defined by the absence of stigmata in the branchial sac. The openings in question (stigmata) are not even such important structures as the primary branchial clefts (gill-sitts), but are merely the secondary slits placing the cavity of the branchial sac in communication with the peribranchial or atrial cavity, and are of nothing like such high morphological value as the presence or absence of a urochord, and of the two prunitive atrio-pores, and the other well-known characteristics employed in former classifications as distinguishing the Appendiculariidae Some of the Thaliacea are placed by Lahille in a group (Hemitremata) of primary importance, by themselves, because they have the stigmata rudimentary or imperfectly formed, while the other Thaliacea are united with all the remaining Tunicata, because they are supposed to be alike in having complete stigmata.

Then, again, an altogether fictitious value is given by Labille to the presence of internal longitudinal bars in the branchial sac, especially since he shows (as had been done by former writers) that these bars develop as outgrowths

[&]quot; "Recherches sur les Tuniciers des Côtes de France " (Toulouse, 1890)

" Which, however, is not really the case " The apertures in the walks - the pranchal sur I Lahille's "Eutremats" are not always homologous retusture". In the genus Cultolius, for example, there are no true stigmatis

from the connecting ducts, and that intermediate conditions can be found in which the bars can neither be slight to be absent nor present. He describes this condition in his new species Perophora banyalenst, and it is also present in P viridit, Vernil, and in various other Simple Ascidians, as has been shown in the Challenger Reports

and elsewhere.

132

Such cases, although rather perplexing to the systematist, are perfectly natural from an evolutionist's point of view, and they certainly make one regard with some suspicion large groups founded upon any auch conclusions. The such consideration of the

Surely Lishille does not serously mean to contend that the internal longutudnal bars in the branchal as of the Botrylldae, Cynthidea, &c, are different in any morphological tense from the similar bars found in other Assistance of the control of the similar bars found in other Assistance of the control of the significant that their relations to the wall of the sac in these two groups, being attached throughout their length in Botryllus in place of only at the angles of the mesbes as in Ascada, and are therefore somewhat different in their development (ontogeny), there on scarcely be any in their development (ontogeny) there can scarcely be any the branchal size as are alike, and are therefore homologous

structures

(3) It follows from what has been said above in regard to the ongin of the Compound Ascidians, that even though the group Polystyelidæ is placed (as was the case in the Challenger Report) in the Ascidiæ Composita: it is not thereby widely separated from its relations amongst the Simple Ascidians. If the sub-order Ascidiæ Compositæ is retained, then the Polystyelidæ must go in it, since they form definite permanent colonies with the ascidiozooids embedded in a common test; but of course these forms are very similar in many respects to Styela and Polycarpa-that being one of the points of contact between Compound and Simple Ascidians—and therefore I tween Compound and Simple Ascignins—and interiors a can agree fully with all that Lacaze-Duthers and Delage say in favour of that relationship. The matter stands simply thus—If Ascidiæ Composite is retained, the Polystyelidæ must be placed in it at the nearest point to Polycarpa amongst Ascidiæ Simplices, while if Ascidiæ Compositæ is abolished, the Polystyelidæ will form a family or a sub-family (it matters little which) alongside the Styelinæ under Ascidiæ Simplices To go further, and break up even the genera of the Polystyelidæ, placing the species beside those Cynthiadæ they resemble most in the structure of the branchial sac, would be to give no value at all to the property of reproduction by gemmation and the formation of colonies.

and the formation of cointies.

(4) It has long been recognized that there are two groups of forms in the family Cynthiudar, those which centre around Sypiel and those related to Cynthia, and when the remarkable stalked forms, such as Boltenia and when the remarkable stalked forms, such as Boltenia the deep-sea genius Culedula, that been added, I defined these three groups as sub-families under the names Stytelinac, Cynthinae, and Bolteninae. Leaving the last

out of the question, we have the two former distinguished amongst other characters by the fact that the Styelinæ have never more than eight folds in the branchal sac, and have simple tentacles, while the Cynthinæ have always more than eight folds, and compound tentacles.

A few years ago these seemed well-established characters to which there were no exceptions. Last year, however, Lacaze-Duthers and Delage published a preliminary account of a Cymbia from the French coasts, with only eight folds (as in Stychine) in its branchial sac; while Trausted four folds on the right ado of the heranchial sac compound (as in Cymthina); and 1 find that long ago Alder described the reverse case in Cymthia. Holder of the compound (as in Cymthina); and 1 find that long ago Alder described the reverse case in Cymthia Nobrovia, Marg, where there are twelve folds in the branchial sac (Cymthia), although the tentacles are simple (Stychina). Stychina have been found, which is perfectly natural and satisfactory to the evolutionist, and the question for the systematist now is, Must these two subfamilies be united? I think not. I believe that they are natural groups, and that they are really as weldy separated more completely isolated from one another by the extraction of intermediate

forms

If these interesting links, to which attention has just been drawn, and which are apparently not common nor widely the better and the state of the state o

(5) The genus Botryllur's seems to contain an endless sense of forms which might be (and many of which have been) described as separate species. Clark, twenty years ago, pointed out the great variability of the species in this genus, and described many varieties and local conditions, but the supply is not yet eshausted, and one is almost tempted to conclude that no satisfactory position can be taken up anywhere between the two extremes of other (1) regarding the whole genus (or even the family Bortyllide); as an enormous protean species, or (2) de-

sections nearly every colony as a separate species.

From the point of view of the systematist or speciographer who wants "good" and well-defined species, this group of Ascedians must be an abomination, but to the student of evolution 11 is full of interest. Here, if anywhere, characters can be seen varying in all

³ Even this difference is not constant. In some Botryllidm, and I think in all Polystycelide and many Cynthidm, the relations of the bars in the adult are precisely as in Ascidia, Come, and Extensection.

These are the chief characters, but there are others, such as the condition of the stomach and digestive glands

directions and to almost all degrees, some variations becoming face while others remain indefinite. I am at present examining (with the help of my former student, Miss A. E. Warhan, B.Sc.) the anatomical characters of a number of colonies of various Bestylius with the view of inding which characters, if any, can be relied on in distinguishing species or "forms," and I are reasonable in which the branchial tentacles, usually regarded as important features in the diagnosis of species, present all variations between eight and sixteen. Every one of the numbers 8, 9, 10, 11, 12, 13, 14, 15, and 3 fo, in represented by one or more saciotosoids, although 8 and 16 are those most commonly found. Also several definite and in the same of t

Il have heard it said, and I fancy it may be often thought, that since evolution has changed our conception of a species, the modern biologist need not concern himself with the description and nomenclature and delimitation of those assemblages of variable forms which the control of the second se

Many of these more general remarks will no doubt apply to other groups of organisms with as much force as to the Tunicata, but some of the instances discussed above may seem points of mere detail of no great general interest. I believe, however, that they are typical cases illustrating difficulties which may confront any specialist continuous many confort are of the proposed object of biological investigations. Autrail or greater classification of animals and plants.

February. W. A. HERDMAN

PHOTO-STELLAR SPECTRA.

PROF. PICKERING, while retaining the four types of stellar spectra, finds that so many stars show an intermediate stage of development, that, in the Draper Catalogue, letters are substituted for the types. Thus, letters A to D denote stars of the first type; E to I, stars of the second type; M, stars of Type III, while N is reserved for fourth type stars. It weemed of some compared to the stars of the second type in the stars of the second type and second types, the observations of Vogel ("Spectra of the stars of the second types, the observations of Vogel ("Spectra of the stars of the second types, the observations of the star of the second types, the observations of the star of the second types, the observations and the star of the second types, the observations are started and tabulated, those being rejected where there was any uncertainty as to type in Vogel's observations. The following table shows the results thus obstanted.—

"Note on the Classification of Star Spectra in vol xxvii Harvani Avnals, and on some Stars with Bright Lines" NO. 1128, VOL. 44]

To show the differences in type, the following table has been drawn up ---

These tables show that, in the case of Type I, nearly half the stars observed with the eye are really Type II according to the photographs; in the case of Type II, four out of the forty, although having a clearly pronounced first type spectrum to the eye, are really second type stars according to the photographs. In the case of the second type, four stars out of forty-two are really first type.

For the third type stars, Dunér ("Sur les Étoiles," &c)
was consulted, and the following results were obtained.—

Dunés Eye observation Type	Pickerine Photographic observation Letter							
III.	V.	F	F	H 19 24	I 2 2	<u>K</u>	М 8 22	
111. !! 111 !!!	3	-	=	16	1	i	24 12	
The set 1				11				

This table may be condensed as follows:--

The photographs therefore show that only 36 per cent are third type at all. In order to account for this very remarkable result, the words of Prof Pickering may be added to the condition of the profit of the state of the state

It will be seen that three stars of the third type appear as first type stars on the photograph These are —

(1) LL 3717, 1h. 55m - 9°0'4, Dunér III " "Les bandes 2-9 sont fortement développées, très larges et sombres."

(2) D M. +17° 1479, 6h 56m. +17'53'8, Dunér III!!
"Tes bandes 2-8, et peut-être 9, sont visibles, elles sont très larges et fort obscures autant dans le vert-bleu que dans le rouge"

(3) "Serpentis, 15h 31m. + 15 25'9, Dunér III "
"Les bandes sont larges et fortes, surtout dans le vert et dans le bleu"

Prof. Pickering states, in the preface, that when the brightness exceeds 6's it is difficult to classify the spectrum with certainty. The photographic magnitudes of these stars are 6 65, 645, 64 et respectively.

As regards the fourth type, it is stated (p. 3) that "the

As regards the fourth type, it is stated (p 3) that "the letter N is reserved for spectra of the fourth type, although no star of this type is bright enough to appear in the Draper Catalogue, owing to the red colour of all such

sters " This seems to be a mistake, as three fourth type stars are found in the Draper Catalogue. They are :-

Name	RA	Decl	Pickering's	Photo	Dupér
D M. +17 1973	8 49+	+ 17 36	. H	6 65	IV. '!!
D M +68 617 D.M, +76 734	10 38	+ 67 56 + 76 22	A? E	6.20 7.08	IV. "

These stars each occur on one plate only.

The photographs show that the following stars have bright lines in their spectra -

Known variable stars . & Aurigæ, a Orionis, (Gemin-

orum, a Herculis, & Pegasi. Suspected variable stars · a Cassiopeiæ, 66 Ceti, p Persei, a Tauri, 8 Canis, 8 Geminorum, a Bootis, 8 Urse

Minoris, & Cygni, y Cephei. Other stars showing bright lines, not hitherto detected,

rer stars snowing origit innes, not intherto detected, are r-Ceti, γ Andromelæ, κ Persei, α Persei, γ Persei, 8ο Tauri, ζ Aurigæ, ζ Cancn, σ' Urse: Majoris, ο Leonis, γ Leonis, ξ Urse Majoris, γ Bootis, γ Scorpii, β Coronæ, ζ Herculis, γ Herculis, μ Herculis T. F. ESPIN

SOME ASPECTS OF STAS'S WORK.

FOR the last thirty years Stas's work has set the standard of excellence in all that relates to atomic weight determination. The literature of the subject teenis with references to his classic memoirs, which have come to be regarded by chemists in the light of canonical books Admiration of the almost magical accuracy of Stas's results seems somewhat to have diverted attention from the rare philosophical insight displayed in the plan of his researches Yet it is not too much to say that, while we owe the conception of the atomic theory to Dalton, Stas first placed the theory on a sound experimental basis.

It was in the year 1843 that Dumas and Stas's value for the atomic weight of carbon recalled attention to the favour on the Continent The subsequent work of Dumas and of de Marignac led these chemists to support the hypothesis in a modified form. In 1860 appeared the first series of Stas's researches, "Sur les Rapport reciproques des Poids atomiques" In the introduction to his paper the author stated his conviction that these researches furnished proof, as complete as the nature of the subject admitted, that the hypothesis of Prout was a pure delusion —that there was, in fact, no common divisor between the atomic weights of the elements. In reviewing the work of Stas, de Marignac admitted the impossibility of reconciling the concordant results obtained by Stas and himself with even the modified form of Prout's hypothesis he regarded the dictum quoted above as too absolute in character It was by no means established, he contended. that the constituents even of stable compounds are present evactly in the proportion of the atomic weights De Marignac's criticism struck at the very basis of the atomic theory but this by no means deprived it of its weight The laws of chemical combination are the experimental basis of the atomic theory, and Stas admitted that these laws had never been proved as "loss mathématiques. Writing in 1865, in the introduction to his "Nouvelles Recherches," he remarks that some of the fundamental ideas of chemistry, which are generally taken as having been proved, are as a matter of fact far from being so. He considers that the constancy of composition of chemical compounds has been experimentally established, but points out that this does not constitute a proof of the law of constant proportions, the law, viz., which states that the particular proportions in which two elements are combined in a certain compound is a constant proportion in all the compounds which contain those elements. This had

NO. 1128. VOL. 441

never been proved, yet it was only in this way that the position of the atomic weights as constants of nature could be established. The so-called law of multiple proportions Stas referred to as an hypothesis of Dalton, pointing out that the very rough analyses on which Dalton relied—of which the error is frequently more than to per cent —as well as the results obtained by Wollaston and by Gay-Lussac, were at most capable of establish-ing a "loi limité." The state of science at the time demanded a thorough re-examination of the basis of the atomic theory Stas realized this need, and took upon himself the burden of the task. The conception and plan of the "Nouvelles Recherches sur les Lois des Proportions Chimiques" show the mind of a great thinker not less clearly than the results of the work exhibit the skill of a master in the art of experiment.
The "Nouvelles Recherches" contains a verification as "loi mathématique" of the law of conservation of mass, in the complete synthesis of silver iodide, and the complete analysis of silver iodate. The constancy of composition of chemical compounds was subjected to a crucial test in the experiments on ammonium chloride, and the constant proportion between the combining weights of elements in different compounds was tested in the conversion of silver iodate, bromate, and chlorate, to the corresponding haloid salts The law of equivalent proportions was verified by the concordant results obtained for the atomic weights of silver and of the alkali metals determined as functions of those of rodine, of bromine, and of chloring respectively, oxygen forming the common stand-ard. One cannot help regretting that the law of multiple proportions was not also made the subject of investigation The most suitable examples occur among gaseous substances, and the operations of gas analysis were foreign to the methods of manipulation employed by Stas. complete analysis of nitrous oxide was indeed contemplated in order to determine directly the atomic weight of nitrogen as a function of that of oxygen, but the idea was abandoned owing to the difficulty of constructing the necessary apparatus.

The work on the laws of combination furnished fresh materials for the examination of Prout's hypothesis Stas's comments on the origin of this hypothesis possess a high degree of philosophic interest The remarks to which we more particularly refer are the following .—" Lorsqu'on remonte à l'origine de l'hypothèse (de Prout) on s'aperçoit immediatement qu'elle doit sa source à un préjugé ou, si l'on veut, à un opinion préconçue, concernant la simplicité des lois de la nature. Pendant longtemps les chimistes comme les physiciens, dès l'instant qu'ils ont vu certains faits se reproduire avec une apparence de régularité, ont ciu λ l'existence d'une loi naturelle susceptible d'être exprimée par une relation mathématique simple. . C'est à cette tendance, d'ailleurs très-naturelle, qu'on doit l'hypothèse de Prout." Dalton's enunciation of the law of multiple proportions is relegated by Stas to the same category as a generalization on insufficient data Mendeleeff has remarked (Faraday Lecture, 1889) that the periodic law has shown that the masses of the atoms increase per saltum, in a manner which "is clearly connected in some way with Dalton's law of multiple proportions." Dalton was more fortunate than Prout combining proportions are expressible by a simple mathematical law, whilst the atomic weights are only to be represented by a complicated formula which may have

some such form as that proposed by Carnelley
The "Nouvelles Recherches" appeared in 1865. first paper on the periodic system was read before the Russian Chemical Society in the spring of 1869. It is curious to reflect that the foundations of the atomic theory had hardly been made sure by Stas ere they were called upon to bear the magnificent structure raised by Mendel

NOTES.

We punt elsewhere the proceedings of the important deputstion to the Board of Trade on the subject of the Institute of Preventive Medicine. There can be no doubt that, after the statement and by the Minnter, the registration of the Society will shortly be an accomplished fact; a few words in the deed of registration or a few minute or freference between the Board of Trade and the Home Office are all that is needed to sufeguard Sir Michael Hicks-Beach's Official scrupter. The importance of the deputatives are the sufficient of the sufficient of the sufficient of the case of the Art Gallery, that men of accidence are no longer willing to be suitabled by men in officience are no longer

THE annual meeting for the election of Fellows was hold at the Royal Society's comes, in Burlington House, on Thursday last, when the following gentlemen were elected into the Society—William Andenson, Pof Frederick Orpes Rower; Sir John Conroy, Bart, 1 Prof Daniel John Cunningham; Dr. George Mercer Dawson, Edwin Bailey Elhot; Frof, Perry Frankay Frankland; Perry C. Gilchnat, Dr. William Dobanson Hallbatton, Oliver Heavatide, John Edward Marr; Ludowy Mond; William Napier Skaw; Prof Silvansa Philips Thompson, Captan Thomas Henry Tarad, R.N.

MR GEORGE HOLT, of Liverpool, last week sent the Treasurer of the University College there a cheepe for ten thousand pounds as endowment for a Char of Physiology, and candidates for the appointment are forthwith to be advertised for. It is only a few weeks since Mr. Brunner, M.P., sent a smular cheque to endow a Chair of Political Economy. The latter post has been offered to and accepted by Mr. E. C. K. Gonner

THE Prince of Wales has fixed 4 o'clock on Wednesday, June 17, for the delivery by Lord Rayleigh of the first of the two lectures at the Royal institution in connection with the centenary of the birth of Michael Faraday, and Friday evening, June 26, 419 o'clock, has been appointed for the second of these lectures, which will be given by Prof Dewar.

STUDENTS of geology were sorry to hear of the death of Dr P. M Duncan, F.R S He died on May 291n his satty-seventh year Dr Duncan was Professor of Geology at King's College, London, and was intimately connected with the Geological Society, of which he was President in 1876 and 1877 He was also a member of the Lunnean Society.

MR G. V Poore, the Government Inspector, who have recently drawn up a report upon experiments performed on luving animals during the year 1850, states that during the hear slyon, states that during the many vults he has paid to places licensed for the performance of such experiments, it has never failen to his lot to see a single animal which appeared to be in boddy pain

WE are glad to be able to announce that Mr [Graham-Kerr, of the University of Edinburgh, Naturalist to the Pilcomayo Expedition, has returned safely to this country, and has succeeded in bringing with him a portion of his natural history collections. As is well known, the Bolsvia, in which Captain Page and his expedition ascended the Pilcomayo, was stranded in that river, in April 1890, in the middle of the Gran Chaco After the death of Captain Page, which occurred while he was returning in a canoe down the Pilcomayo to get medical assistance, the Bolsvia remained stuck fast nearly in one spot until March of this year, when Mr. Kerr, finding the vessel still immovable, and no prospects whatever of a rise in the river, decided to come away as best he could After a very rough journey he reached Asuncion on mule-back, bringing as many of his light things as possible, and arrived in this country last week Some very interesting letters of Mr Kerr's, describing the natural history of the Gran Chaco, will be found in the two numbers of the Ibis for January and April last.

NO. 1128, VOL. 44

UNDER the will of Dr Fothergill (1821), funds were bequeathed to the Society of Arts for the offer of medals for subjects, in the first instance, relating to the prevention of fire A Society's Gold Medal, or \(\inf 20\), is now offered for the best invention having for its object the prevention or extinction of fires in thetries or other places of public amusement

MESSRS, NEWTON AND Co, have been appointed philosophical instrument makers to the Royal Institution of Great Britain, an appointment which we believe has not been held by any firm for some years

MR JOHN T BRUNNER, MP, has been elected President of the Sanday Society in succession to Prof. G. J. Romenes, Mr. Brunner will deliver his presidential address at the Society's public annual meeting on June 27

Till Societé Botanique de France recently held it, annual meeting in the little town of Colloure, near Perpignan, on the Mediterranean coast. After the meeting many excursions were made in the neighbourhood, which is interesting to botanists

On behalf of Prof F C Stirling, of the University of Adelaide, South Australia, Prof. Newton communicated to the Zoological Society of London, at its meeting last week, a figure of the new Australian Marsupial, originally described by Dr Stirling in this journal in 1888 (NATURE, vol xxxviii p. 588), together with some notes on this extraordinary animal. Notorycles typhleps, as Dr Stirling now proposes to call it, is a small molelike animal belonging to the order of Marsuptals, of which it forms an entirely new type A general description of it has already been given, as above referred to, but Prof. Stirling now adds that the Marsupial hones are exceedingly small nodules, and escaped his notice at first. Four or five of the cervical vertebræ are fused, and there is a keeled sternum, an enormously thick and short first rib, which serves a purpose of buttressing the sternum in lieu of coracoids, and a bird-like pelvis. The penis is in the uro-genital canal, and the testes are external in front of it. The eyes are mere spots underneath the skin. The four specimens as yet received of Notorycles typhlogs were obtained in the centre of Australia, on the telegraph line between Adelaide and Port Darwin The animal is said to burrow in the sand with great rapidity A full description of it, it is understood, has appeared in the Transactions of the Royal Society of South Australia, but no copy of this journal has as vet reached England

MM. Grehan'r and Quinquaud conclude from some recent experiments on dogs that under the influence of alcohol muscular strength is much diminished.

PROF JOHN M. COULTER, the well-known botanist, has been elected President of the State University of Indiana, located at Bloomington, and Dr. Douglas H. Campbell has been appointed Associate Professor of Botany at the new Stanford University of California

ACCORDING to the Botanucal Gazette, Mr. Thomas Mechan, of l'hiladelphas, is about to establish, in conjunction with his sons, a new journal of gardening and botanucal miscellany it will be called Mechan's Monthly, and the first number will appear on July.

We learn from the Journal of Eddary that Mr. Worthungton G Smith is preparing for the public gallery of the Bonanical Department of the British Museum a series of 66 tables illutrating the British Fungs. Every species of the Hymenomycetes will be figured in its natural colours, the drawings being taken from Mr. Smith's own series already in the Museum, with others from ongual figures tent by Mr. Flowraght and others.

THE number of Neptunia for April 30 gives a brief description of the following stations for the study of natural history ---

A marine mological station has been founded at Endoume, near Marsellies, by Frof. Marone, specially for the study of the fabre of the Mediterranean. M. Alphonne Bioson is about to establish at his own expense a coological station at Fount-de-Grave, Gironde, with the especial object of promoting the investigation of the omithology and eniomology of the district A marine station for physiology has been opened at Tamania, Physiology in the Facility of Stepces at Lorina.

The Berlin Academy of Sciences has recently made the following grants:—£(100 to Dr Fleischmann, of Erlangen, for researches in development; £30 owards the cost of publication of Dr. Krabbe's work, "Development-Huttory and Morphology of the polymorphous Lichen Genus Cidadoma", £60 to Dr. Hartwig, of Bamberg Observatory, towards a sense of observation on variation of the earth's ass, and £60 to Dr. Schmidt, of Halle, for researches on the light reflected from transparent bodies.

THE following are subjects for prize competition, recently proposed by the Belgian Academy of Sciences .- Advancement of our knowledge of the relation of phenomena of solution to phenomena of combinations, discussion, on the basis of new experiments, of works relating to the kinetic theory of gases, perfection of the theory of approximative integration, both as regards rigour of methods and facility of application, researches on the embryonal development of a mammal belonging to an order the embryogeny of which has not yet been investigated . determination, by means of palgeontology and stratigraphy, of the relations between formations referred by Dumont to his Lackenian and Tongrian marine systems, new researches on the formation of polar bodies of animals The prizes are gold medals, of the value of 1000, 800, and 600 francs Papers to be written in French, Flemish, or Latin, and sent to the Secretary before August 1, 1892

MRSSAS RICHARD FARRES have issued an illustrated catalogue of measuring, controlling, and self-registering instruments for scientific and industrial purposes. A descriptive and illustrated list of instruments has also been published by the Cambridge Sensitis Instrument Company.

THE series of lectures annually given in the gardens of the Royal Botanic Society of London upon subjects connected with botany came to an end on Friday last, when Prof. Stewart, F.R.S., President of the Linnean Society, addressed a large number of visitors and students upon "The Relationship between Plants and Animals." The subject, he said, was one of much interest, as affording an explanation of the origin of many abnormal forms of vegetable growth. This is specially the case in tropical countries, where the struggle for existence is more intense than in colder climes , there the relationship is almost vital, some plants providing food, others shelter, to various kinds of ants, while these pugnacious insects, in turn, protect the plant from damage, by attacking any living thing which approaches it. One plant, known as the bull's-horn acacia, of Central America, provides a species of ant not only with food and drink, in the shape of tiny egg-like bodies upon the leaves-of which the ants are very fond-and a sweet fluid in special cavities on the stalk, but, su addition, furnishes a home in the hollow somes with which it is armed, these, when punctured by the ants, swelling out into perfect miniature bull's horns. In return the ants protect it from its enemies.

A SERIES of experiments with regard to evaporation from free water surfaces and from earth saturated with water, in sun and an shade, has been recently made by Signor Battelli (IT Numos Cusents) He used three large tube or vats, two holding water, and the third earth on a grating, to which water was admini-

from a pipe entering the bottom. One water-tub and the earthtub stood a few yards apart on the north side of a high wall : the other water tub was in the open, and embedded in the ground. Signor Battelli's results are these .- The quantity of water evaporated from moust earth is in general greater than that from a free stagnant water surface, when the air temperature rises ; but less, when the latter falls. With increasing wind-velocity, evaporation increases more rapidly from the water surface. The moister the air, the greater (other things equal) seems to be the ratio of the water evaporated from the moist earth to that from the stagnant water surface. The evaporation of a water surface exposed to the sun's rays is greater than that of a shaded one. not only by day, but in the following night With rising temperature, the ratio between the water quantities from these two surfaces increases somewhat more quickly, with rising windvelocity, this ratio diminishes

THE. Photographic Journal of May 22 prints a paper by M. Lon Vidal, on photographic methods of obtaining polychromatic impressions. One of the writer's objects is to show that typographic and lithographic printers ought to find in photography "one of their principal satisfaces." By its ad, he says, their work might be executed "more cheaply, more thoroughly, and more artistically."

On Sunday, June 7, there was a series of severe earthquake shocks in Italy. The centre of the seismic movement seems to have been in the province of Verona, but the disturbance was felt over a wide area. At Verona three strong shocks, preceded by a subterranean noise like the roaring of artillery, are reported to have occurred at 2 o'clock a m The inhabitants rushed in terror from their houses to seek safety in the open streets and squares One of the assistant mistresses at a boarding-school died of fright A number of chimneys were thrown down by the oscillation Still more violent were the effects of the seismic disturbance at other places in the province of Verona, especially at Tregnago and Badia-Calavena Shocks more or less severe were experienced at Brescis, Belluno, Ravenna, Parma, Modens, and Ferrara. The Central Meteorological Bureau reports that the earthquake was very strongly felt at l'Iorence, where it awoke several people from their sleep. The disturbance also extended to Rome, as was shown by the seismograph, the time nt which the shock was felt in Rome being 6 minutes and 40 seconds after 2 a m. In Verons and the surrounding districts slight shocks continued to be felt on Monday and Tuesday. A large stream of lava issued on Monday from the new crater of Mount Vesuvius at the base of the central cone. Signor Palmieri, the Director of the Vesuvian Observatory, holds that this flow is directly connected with the earthquake shocks in the north, and points out that seismic disturbances in Italy generally stop when the eruption of Vesuvius begins.

In the Report of the Meteorological Service of the Dominion of Canada for the year ending December 31, 1887, just issued, it is stated that nearly eleven hundred warnings of approaching storms were issued by the Service during the year, and that of these warnings 972 were verified, being 8879 per cent.

We have the pleasure of recording the issue of the first wolume of the Poblications of the Vancan Observatory, containing astronomical and meteorological observations for the last nine months of 1890. This Observatory was first established by Pope Gregory XIII for astronomical purposes, and was need for regular meteorological observations from 1800-1821. After passing through several vicinitudes, a proposal was made, about the time of the Valucial publice Exhibition in 1888, to recorganize the Observatory, and the present Pope accordingly the resultablesh or no a sound basis, and it is now furnished with the best instruments procurable, both for direct observators and continuous registration in meteorology, astronomy, mag

netum, and earthquake phenomena. It is proposed to carry on varous researches, and to issue further volumes from time to tume, as soon as sufficient materials are accumulated The Director is Padre Denza, the founder of the Italian Meteorological Society, and Superintendent of the Observatory at Moncalatri.

CONSIDERING the question of determination of the evaporating power of a climate, Dr. Ule distinguishes (Met Zests.) between the intensity and the speed of evaporation The latter can be well determined with an instrument like Wild's evaporimeter. and Dr Ule sets forth, in a table, the monthly data of this for Chempitz, compared with those of absolute humidity. "saturation deficit," and relative humidity. The agreement of the last with the evaporimeter figures is much better than that of the two others : still, there is considerable discrepance, and this is not explained (the author shows) by variations in windintensity. On the other hand, the data of the psychrometer show a remarkable parallelism with those of the evaporimeter, and by taking wind-variations into account the agreement is sucreased. Thus, from psychrometer differences and wind variations, the evaporative power of a climate may be correctly estimated where an evaporimeter is wanting. Dr. Ule offers a new formula for estimating the layer of water evaporated in a given time, and tests it with two German climates, and one Australian

In an interesting paper on technoal education in agriculture, respirated from the Journal of the Koyal Agricultural Society, Dr. W. Fream refers incidentally to the value of mathematical studies for the agricultural. Dr. Fream's professional expensions at agricultural colleges has convinced him that a lad who is a starty completant in mathematical usides is "a good medium to work upon," "Those interested in the welfare of any young agricultural, stool did take care," he say, "that in his school days the study of mathematics is not ignored. The time devoted to acquiring professioner, in arithmetic, geometry, emissiration, and the elements of algebra and trigonometry—the latter really indispensable in the case of surveying—will never be regretted."

THOSE who are interested in questions relating to physical education will find much to please them in an excellent paper. in the lune number of Physique, on natural history in public schools, by the Rev T. A Preston, late President of the Marlborough College Natural History Society. Many boys are not much attracted by games, and it seems hard that in such cases any sort of compulsion should be used. Why not have various alternative ways of securing exercise, any one of which might be chosen? Mr. Preston shows with great force, and in a very interesting manner, with how much advantage the study of natural history might in some instances be substituted for cricket and football. Boys out for a field excursion take a great deal more exercise, he maintains, than is ever taken at cricket. "With those who are keen naturalists," he says, "the mere exercise taken in any one day (not in an excursion) is often such that it might almost be said to require moderating I have no hesitation in saying that, if exercise alone is to be considered, a field naturalist will take far more than any one at games.'

ME. W. R. HILLIER, of the Indianc Unil Service, has written a very circius monograph on the manners and outsons of the Shan States. When a Shan becomes a father it is considered highly undersinght buth the should drive pige, carry the dead, tower holes, fill in holes in the ground, or indiage is monetime to the body. Hore buth, in Hillier, "the without marrying, the body, here buth, in Hillier, "the without marrying, the body, here buth, in Hillier, "the without marrying the body, here buth, in Hillier, "the without marrying the body, here buth, in Hillier, "the without marrying that body, here is the body, here are the body here considered as representing the husband or wisit."

unrequited affection in the next stage of existence is simplicity itself. A young man takes a fancy to a young lady, and if the liking is reciprocated, she straightway accompanies him to his house as his wife. Next day the young man's parents meet the parents of the young lady, and after informing them of what has taken place, beg that "they may be forgiven for the intrusion," and ask that a day be fixed for the wedding This request being granted-and apparently a refusal is not contemplated-the young lady returns to her parents. Divorce is easy also, the man merely giving his wife a letter permitting her to remarry, and the wife merely being required to pay an unwilling husband thirty rupees for release from an uncongenial mate As to food the Shan is not an epicure, eating everything that is eatable; and indeed it is considered quite becoming, if he only be of high rank, to devour an enemy This privilege, however, is accorded only to Bohs, or chiefs The Shan theory of the cosmorony is that "the earth came out of the depths by means of white ants."

Some further explorations have lately been made on the Upper Irrawaddy Major Hobday, of the Indian Survey Department, with an escort of fifty Goorkhas, succeeded in getting as far north as latitude 26° 15' up the Malika, or right branch of the river. Here the local tribes began to show opposition, and the party could not without fighting their way have proceeded further The point reached was, however, only fifty miles south of that which Colonel Woodthorpe gained a few years ago in his ex-plorations from the far north of Assam This small gap will prohably be crossed when the next attempt is made, as by that time the wild tribes will have learned from their neighbours that British officers have only friendly intentions towards them Finding his progress barred to the north, Major Hobday turned due eastwards, with the intention of striking the Meka, which is supposed to be the main stream of the Irrawaddy. After exploring the course of this river for some distance, he will journey back through the hills along the Yunnan border, reaching Bhamo by land. He will thus be able to map a considerable extent of country.

An interesting synthesis of troilite, the crystallized monosulphide of iron. FeS, which is so frequently found in meteorites and yet is never found in terrestrial rocks, is described by Dr Richard Lorenz, of Gottingen, in the current number of the Berichte, A stream of dry sulphuretted hydrogen gas was led over a bundle of iron wire contained in a combustion tube heated in a furnace As soon as the wire became heated to dull redness, it became quite changed, becoming completely covered with innumerable brilliant little crystals. These crystals possessed a bright silver white lustre when first obtained, but after a short time reflected a pale-green coloured light. On standing for some days, the crystals further changed in colour to blue and afterwards to brown, without the least change in the form being apparent. Under the microscope they appear to consist of wellformed six-sided tables of a bright steel-gray lustre. Prof. Groth, the eminent crystallographer, who has examined them, pronounces them to be hemimorphic hexagonal in form, isomorphous with wurtzite, the hexagonal variety of zinc sulphide, Any kind of iron may be substituted for the wire; whatever the variety employed, it always becomes covered with a crust of these crystals when heated in a stream of sulphuretted hydrogen, the only precaution necessary being to prevent the temperature from rising to the melting-point of monosulphide of iron. The crystals are readily detached from the iron, and upon analysis yield numbers very near the theoretical ones required by Feb The largest and best developed individual crystals of troilite are obtained by diluting the sulphuretted hydrogen with an inert gas. Wurtzue, sulphide of zinc, ZnS, may also be readily artificially obtained in a similar manner by passing sulphuretted

hydrogen over zinc heated to whiteness in a porcelain tube in a Schlosing furnace. When the tube, which is allowed to cool in the stream of gas, is broken, immediately beyond the portion which has been heated in the furnace a beautiful sublimate of crystals of wurtzue is found. They consist of well developed hexagonal prisms, somewhat transparent and of a yellow colour. exhibiting, according to Prof. Groth, their hemimorphic nature in a most decided manner. In a similar way also Dr. Lorenz has artificially prepared greenockite, aniphide of cadmium, CdS. This synthesis is perhaps the easiest of all to effect, and it may readily be conducted in an ordinary combustion-tube. The metallic cadmium is placed in a porcelain boat, and commences to react with the sulphuretted hydrogen at a temperature just below its boiling-point. As soon as this temperature is attained, the porcelain boat and the portion of the tube beyond it become covered with magnificent long yellow skewer-like crystals of greenockite, which Prof Groth finds to be of two kinds, hexagonal prisms isomorphous with troilite and wurtzite. and a new form of greenockite consisting of monoclinic crystals Dr. Lorenz has further artificially prepared millerite, the sulphide of nickel, NiS, by the same method, obtaining in this case very minute but undoubtedly hexagonal crystals isomorphous with the three other sulphides above deserrbed.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (Macacus cynomolgus ?) from India, presented by Mr. Walter Fraser, a Rhesus Monkey (Maracus rhesus 9) from India, presented by Colonel Beresford . a Great Black-headed Gull (Larus schthyactus) from the Persian Gulf, four Macqueen's Bustards (Houbara macqueens & & 9 9) from Western Asia, three Chaplin Crows (Corvus capellanus) from Persla, presented by Mr B. T. Ffinch, C M Z.S.; a Diamond Snake (Morelia spilotes) from New South Wale-, presented by Mr. J Hellberg; a Common Viper (Vipera herus) from Hampshire, presented by Mr W. H. B Pain; two Piapecs (Ptilostomus senegalensis) from West Africa, purchased . a Colleged Fruit Bat (Cononycters; collasss), four North African Jackals (Canss anthus), two Partridge Bronze-wing Pigeons (Geophaps scripta), bred in the Gardens

OUR ASTRONOMICAL COLUMN

THE SPECTAR OF DOUBLE STARS —A note on "The Discovery of Double Stars by means of their Species", No. 5034 by Fed S. C. Federant to Astronomote Padarthetin, No. 5034 by Fed S. C. Federant to Astronomote Padarthetin, No. 5034 species, relative orbital motion in the line of sight may cause a specific doubling of the lines. Bin if the species he not similar any lines common to both ought to be conspiciously strong, and, provided the components have not equal and opposite velocities in the line of sight, ought also to be displaced with reference to other lines. Thus, if one component of a close binary system other lines. I hus, il one component of a close binary system has a Group V spectrum, like our sun, and the other a Group IV. spectru u, in which strongly marked hydrogen lines is the main feature, the resulting spectrum will have a composite character, and careful measurements should show that the position of the hydrogen line is periodically displaced when compared with the lines characteristic of the solar type spectrum a Canis with the lines characteristic of the solar type spectrum. Am Mayoris is the brightest star having this composities spectrums, and the wave-length of the hydrogen line. G. derived from a comparison with sights lines of greater and three lines of annalier and the second of the second appear cannot me pretentences as one to the results absorbed as a composed one quaranties of the composed of the second, as compared with the bright component. An examination when their the following stars have the composite spectrum effected to , 7 shoulmoneds, 11, 65 op., 160 or., a storying and the following disruption of District of the composite spectrum of the following disruption of District of the Composite Secondary of the Composite Seconda

distinctly separated from those of the chief stars. Although the distinctly separated from those of the chief stars. Although the strong hydrogen lines in the spectra investigated may be due to the presence of a faint companion, their intensity may also be due to many other causes. That, the strong hydrogen lines in the solar spectrum are not due to the integration of the spectrum of the sun and that of a companion. It is necessary, therefore, to determine whether the displacement is subject to a periodic variation or no, in order to test this method of discovering dose binaries

THE PERSEID RADIANT.—At the St. Petersburg Academy of Sciences, on April 22, M Bredichin concluded, from the meteor observations made at Pulkova by ten astronomers in August 1890, "le courant des acrolithes n'est pas délimité par un point ou un petit rond, mais présente une surface considérable parsemée de radiants."

THE FLORA OF DIAMOND ISLAND.

DIAMOND ISLAND is situated at the mouth of the Bass JIAMUND ISLAND is situated at the mouth of the Basseth River, in the Indian Ocean, about five miles from Pagoda Point and eight miles from Cape Negrasi, and in about 16. NI lail. It is of vanistione formation, somewhat exceeds a square inlie in area, being about twice as long as broad, and the central part is a kind of plateau 60 feet or so above the level of the sea. With the exception of a small clearing for a telegraph station, the shad as densely wooded down to the sea, but there swatten, the residual agencies woodca down to the see, but there is no inangrove belt on any part of the sandy coast, unless it be considered as represented by a few patches of Avicenna of plantatis. Thus is the siland described, though in greater detail, by Dr D Frain, Curator of the Herbartum of the Royal Bolanic Garden, Calcutta, who has visited the island in H M. Botanic Carcen, Carcutta, who has visited the issand in It at.

Indian Marine Survey steamer Investigator, commanded by R.

If Ioskyn, R N. Dr Prsin has published an elaborate analytical account of the flora in the Journal of the Asiatic Society of Bengal. He collected eighty-six species of flowering plants, three ferns, and four funguses, among which there was not a single novelty. The enumeration includes a number of cultivated plants, among them the coco nut paim; but these are all of recent introduction. It is supposed that the island was not previously inhabited, and therefore that the vegetation of the dense wood overspreading the island is quite natural. The most in-teresting fact brought out is the evident affinity with the somewhat distant Andaman flora, pointing to a former connection.
The Report is also valuable to the student of plant-distribution for the details it contains of the habitats and relative frequency of the component species of the vegetation

W. BOTTING HEMSLEY.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE,-Lord Walsingham, F R S., the High Steward elect, has issued a letter of thanks to the Senate, in which he promises to maintain the highest traditions of "our belowed University

M Hicks, F R S, late Fellow of St. John's College, and Principal of Firth College, Sheffield, has been approved for the degree of Doctor in Science. Dr. Hicks is the author of many important memours in mathematical physics, and of an approved

text-book of dynamics
Prof Newton has been appointed a Manager of the Balfour From Newton has been appointed a Manager of the Bailour Studentship Fund for five years.

A. H. L. Newstead, Scholar of Christ's, and E. W. Mac-Bride, Scholar of St. John's, and President of the Union Society, have been nonunated for research work at the Naples Zoological.

Station The Syndicate appointed for the purpose have selected a site for the Sedgwick Memonal Museum on the old Botanic Garden area, with a frontage to Dowaing Street. The proposed Museum will lie between the new Chemical Laboratory and the old Anatomical School, and complete one quadrangle of the new

The Annual Report of the University Observatory contains a

good record of work done and in progress Prof Adams is to be congratulated on the satisfactory way in which, notwith-standing his long and severe illness, the Observatory has been conducted

SOCIETIES AND ACADEMIES. LONDON.

Royal Society, May 14,—"On the Theory of Electro-dynamics" By I Larmor, Fellow of St John's College, Cambridge Communicated by Prof J J Thomson, F R S. The electrical ideas of Clerk Maxwell, which were cultivated partly in relaxion to mechanical models of electrodynamic action, led him to the general principle that electrical currents always flow round complete circults

When this principle of circuital currents is postulated, the theory of electrodynamics is reduced to the Ampère-Neumann theory of complete circuits, of which the trath has been fully established. It leads, as shown by Maxwell, to the propagation of electrical action in dielectric ments by waves of transverse electric displacement, which have the intimate relations to waves

electric displacement, which have the intimate relations to wares of light that are now well known.

The problem of determining how far these remarkable conclusions will still hold good when a more general view of the nature of dielectric polarization is assumed was considered by von Helmholtz in a series of memoirs

The most general conception of the polarization of a medium which has been formed is the Poisson theory of magnetization. The magnetized element, whether actually produced by the orientation of polar molecules, or otherwise, may be mathematically considered to be formed by the displacement of a matically considered to be formed by the displacement of a quantity olicida imagenic matter from an angiture to its posi-tive pole, thereby producing defect at the one end, and excess tive pole, thereby producing defect at the one end, and excess moment, which is the product of the shipping displaced by its moment, which is the product of the shipping displacement per distance through which it is displaced. The displacement per unit volume, neasured by the product, re equal to the magnetic moment per unit volume, whether the magnetized molecules full with momentum launch between the mysterior of discrete particles with momentum launch between them systems of discrete particles with unoccupied space between them

In the electric analogue we replace ideal magnetic matter by ideal electric matter; the displacement thus measured constitutes the electric displacement, and its rate of change per unit tutes une electric despitements, and its rate of change per unit time represents the dispitacement current in the dielectric. We have to consider whether a deplacement current of this type suf-fices to make all electric currents ericuital; and it will be suffi-clent and convenient to examine the case of a condenser which

is charged through a wire connecting its two plates. In the first place, this notion of electric displacement leads to the sam distribution of potential between the plates as the ordinary one, adopted by Maxwell, for in the theory of induced magnetism netic induction of Maxwell, of which the components are $-\mu(d V/dx)$, $-\mu(d V/dy)$, $-\mu(d V/dz)$, and which, therefore, eads to the characteristic equation of the potential

$$\frac{d}{dx}\left(\mu\frac{dV}{dx}\right) + \frac{d}{dy}\left(\mu\frac{dV}{dy}\right) + \frac{d}{dz}\left(\mu\frac{dV}{dz}\right) = 0,$$

corresponding to the one given above. If the displacement in the dielectric is $-\kappa(dV/dx)$, $-\kappa(dV/dx)$, $-\kappa(dV/dx)$, then

$$u = 1 + 4\pi\kappa$$

The displacement in a unit cube may, of course, be considered as a displacement across the opposite faces of the cube.

Now, considering the case of a plane condenser, let F be the Now, considering the case of a plane concenses, let x be the electric force in the dielectric between the plates, then the displacement is xF. Let o be the surface density of the charge conducted to a plate, then the effective electrification along that plate will be of surface density $\sigma' = \sigma - \kappa F$, therefore, by Coulomb's principle.

so that
$$\begin{aligned} \mathbf{F} &= 4\pi\sigma' \\ &= 4\pi(\sigma - \kappa \mathbf{F}) , \\ \sigma &= \frac{\mu}{4\pi} \mathbf{F} = \kappa \mathbf{F} + \frac{1}{4\pi} \mathbf{F} \end{aligned}$$

Thus the current is not circuital, but there is an excess of the surface density conducted to the surface over the displacement current from the surface, which is equal to F/4*.

The specific inductive capacity, as determined by static experiments on capacity, is here measured by μ , the coefficient in the expression for σ

In addition to this discontinuity at the face of a condenser pinte, the induction in the mass of the dielectric will not be circuital unless the electric force is itself circuital, which it is not in the general form of the electrodynamic theory. The most general type of electrodynamic relations which is consistent with the established theory of complete circuits, is discussed on the basis of you licimholta's work, but with

avoidance of certain restricting conditions introduced by him, the chief conclusion being a follows in a complete circuit the one thing essential to the established theory is that the electric force integrated round the circuit should be equal to the time rate of change of the inagnetic induction through it, and, therefore, have an ascertainable value, though

its distribution round the circuit is a subject of hypothesis. conclusion that waves of tran-verse di-placement will be propagated in a dielectric with velocity $kt^{-\frac{1}{2}}$ will hold good if we assume any form whatever for the electric force which does not violate this one relation, and also assume an electrostatic violate this one relation, and also assume an electrostatic polarization of the medium, equal at each point to the electric force multiplied by a contant K₁/4w.

The increased generality which can be imparted to the theory

merely leads to various modes of propagation of a condensational wave

If K2 denote the specific inductive capacity of the medium, measured in static units, this polarization constant K_1 is equal to $K_2 = 1$, and the velocity of the transverse waves is the ratio of the electric units of quantity in a medium of unit inductwo capacity multiplied by the static value of K_1^{-4} . The correspondence of the refractive index for the simpler media with K_2^{-3} , as well as direct measures of the relative velocities of electric waves in other media, give for the value of this velocity the same ratio multiplied by $K_s^{-\frac{1}{2}}$ These values can be reconciled only by the liming form of the theory of polarization which is equivalent to Maxwell's theory.

"Method of Indexing Finger Marks." By Francis Galton.

F.R.S. F. K.S.
Sufficient proof was adduced by me in a memoir read November 27, 1890, before the Royal Society (Phil. Trans., B, 1891), of the extraordinary persistence of the papillary ridges on the inner surface of the hands throughout life 1 was shown that the impression in ink upon paper of each finger tip, contained on the average from twenty-five to thirty distinct points tained on the average from twenty-five to thirty distinct points of reference, every one of which, with the rarest exception, appeared to be absolutely persistent. Consequently that it was possible to affirm with practical certainty whether or no any two submitted impressions were made by the fingers of the same

person.

In the present memoir I shall explain the way in which finger
prints may be indexed and referred to after the fashion of a
dictionary, and on the same general principle as that devised by
A Berulion with respect to anthropometric measures, whose ingenious method is now in regular use on a very large scale in the criminal administration of France and elsewhere. I desire to show how vastly the practical efficiency of any such method as that of A. Berullon admits of being increased by taking finger prints into account in the way to be described.

larger pints into account in the way to be described. It must not, however, be supposed that the use of indexing finger marks is limited to the shore purpose, the power of doing so being equally needed for racial and herefathary inquiries I do not dwell upon these applications now, simply because I am engaged in making them, and the results are not yet ready to be published. I ought, however, to mention that a great increase published I ought, however, to mention that a great increase of experience has fully confirmed my earlier wears, that flagger of experience has fully confirmed my earlier wears, that flagger study owing to many distinct reasons. The impressions are easily to be made by anyone who has the proper appliances at hard. They are as darable as may other prested matter, and and clear, and their similar are made pendent of age and growth They are necessarily tra-tworthy, and no reluctance is shown in permitting them to be taken, which can be founded where upon one of the contraction of personal vanity or upon an unwillingness to communicate un-desirable family peculiarities

Without caring to dwell on many of my earlier failures to index the finger prints in a satisfactory way, my description shall be confined to that which has proved to be a success. It is based on a small variety of conspicuous differences of pattern in each of many digits, and not upon the numerous minute peculiarities of a single digit. My conclusions are principally based on a study of the impressions of all 10 digits of 289 different persons, but the tables given in the memoir refer only to the first 100 on my list. These are sufficiently numerous to serve as a fair sample of what we might always expect to find, while

they are not too cumbrous to print and to discuss in full detail Though I have spoken and shall speak only of impressions, it is not really necessary in forming an index to make any impression at all. All the entries that appear in it may be derived directly from the fingers themselves.

directly from the ingers inemselves. I rely, for the purpose of indexing, on the three elementary divisions of primaries, whoris, and loops. They are severally expressed by the numerals I and 2, 3 and 4, 5 and 6. The reason of this double numeration is that most of the patterns. reason of this double nimeration is that most of the patterns have a definite axis. Those that are formed by ridges which proceed from only one side of the finger, he in a sloping direction across its axis, the slope being directed according to the side from which the supply of nidges proceeds. All normal slopes, or chose that are (roughly) parallel to a line drawn from the tip of the forefinger to the base of the luttle finger, as well as all the patterns that have no definite axis, are expressed by the by the even numerals 2, 4, or 6. It cannot be too strongly insisted that the words right and left are ambiguous, and must not

be used here.

The forefingers are the most variable of all the digits in respect to their patterns, their slopes being almost as frequently

NO. 1128, VOL. 44]

abnormal as not, the third fingers rank next; the little finger ranks last, as its pattern is a loop in nine cases out of ten. I therefore found it convenient not to index the fingers in their therefore found it convenient not to index the fingers in their natural order, but so that the sequence of the namerals which express the patterns on the digits should be divided into two groups of three numerals, and two groups of two numerals. so 355. 455. 553. 55. The first group 355 referring to the first, second, and thred fingers of the left hand; the second group 455 to the first, second, and third fingers of the right hand, the third group 55 to the thumb and fourth finger of the left hand, the fourth group 35 to the thumb and fourth finger of the right hand. The index is arranged in the numerical sequence of these sets of numbers

these sets of numbers

Before translating the patterns into numerals, I find it an
excellent plan to draw symbolic pictures of the several patterns in
the order in which they appear in the impression, or in the fingers themselves, as the case may be, confining myself to a limited number of symbols [a list of those which have thus far sufficed number of symbols [a list of those which have thus far sufficed as given in the memor r, 50 them are symmetrical yearbols, and as given in the memor r, 50 them are symmetrical yearbols, and each pair being inclined to the right, and the other to the left. The total number of these heretylphs is consequently 3]. A little violence has of course to be used now and then, and the symmetrical transfer of the state of the st where the same reture does any for inferent soluting, as in the words at, ask, ale, and all. The ments of this process are many. It facilitates a leasurely revision of first determinations, it affords an adequate record of the character of each pattern, it prevents mistakes between normal and abnormal slopes, it prevents confusion when changing the sequence of the entries from the order of the impressions to that used in the index, and, lastly, it affords considerable help to a yet further subdivision of the patterns

In making a large and complete index, the symbols would, of course, be cast as movable types, and be printed with the letter-

It appears from the 100 cases that are printed in the memoir that there were 83 different varieties of index numbers when all 10 digits are used Consequently the average number of references required to pick out a single well-defined case from among these too would be equal to 100 divided by 83—that is, to about 1; I do not expect from my own relicrated experiences that there would be much trouble due to transitional cases, after a standard collection of doubtful forms had been collected and numbered. so as to insure that different persons should follow a common I find much uniformity in my own judgment standard

standard. I find much uniformity in my own judgment. Owning to the large effect of correlation, as mides based on all Compa to the large effect of correlation, as mides based on the large effect of correlation, as the large effect of the large ef

tion, or bad scars, or obliteration due to some exceptional cause tion, or bad acase, or obliteration due to some exceptional cause maybe reader of value. The three fingers of both hands are more than two cas useful for an index as those of one hand only, again, the three fingers of one hand a energy two cases as useful as a superior of the sound of the contract of

the same index number, in order to find a duplicate of a particular speciment, it is a very expelitions method to fix on some one well-marked characteristic of a mustle kind, such as in many present tisself in any one of the fingers, and in making the search to use a lens or lenses of low power, fixed at the end of an arm, and to confine the attention to selly to looking for that one characteristic. The cards on which the finger marks have been inside, may then be passed societatively under the lens with

uceu msos, may men ue passed successively under the lens with great rapidity. [It is proposed to exhibit specimens illustrative of this and of the previous memoir, together with appliances for taking impressions from the fingers, at the approaching sourie of the Koyal Society.]

Physical Society, May 22—Prof W E. Ayrton, F.R.S., President, in the chair.—Mr. C. J Woodward exhibited Dr. Schobben's form of lanters attereouspee, This instrument consists of a double lastern, by which the two pertures of a stereoscopic alide are projected on a screen. The two pertures are colored complementary time by planing pieces of red and green than the consistency of the project of th glass in front of the leases, and each observer views the over-lapping images intrough speciated, the eye-glasses of which are also coloured red and green. The atterescopic effect is very striking. Mr. Boys stated that he had treet to obtain a smillar result with the sid of polarized light, hy vaewing two polarized interesting the principle of the effect was obsained, owing to efficie oblistication produced by the screen, but he thought that it a deed gold cereft had been used instead of a nordningone, the effect might have been observed.—Prof Perry, F.R.S., showed a new form of steam-engine indicator. A galvanometer knowed a new form of steam-engine indicator. A gavanometer mirror is fixed excentrically to a steel disk, forming one side of a chamber communicating with the cylinder The pressure of the steam bulges out the disk, and causes the mirror to deflect a ray of light thrown on it in the ordinary way. A rotation of the mirror at right angles to the former is imparted by the movement of the at right angles to the former is impared by the movement of the putsor-tod. The ray of light trees, out the dangemen on a screen owing to the persistence of impressions. This indicator po-seess advantages over other form, he being free from errors due to friction or oscillations of the springs, and the alteration of continuous difference of the street of the street of the ordinary indicators are considerable at high speech, owing to the ripples introduced into the indicator diagram. If the natural period of the apprais a none-twentile of the time of a revoluperiod of the springs is one-twentieth of the time of a revolu-ion, the diagram is fairly free from ripples, but if it is as much as one-tenth, no amount of friction in the inductor will present pipples forming. In the new inductor, the natural period of removable, and can be proportioned to said different pressures and speeds. For experimental and testing purposes it is advant-ageous to see at once the alterations in the diagram caused by changes of lond, pressure, &c. Several diagrams were exhibited to the meeting. In reply to Trof Caru Wilson, Prof Perry stated that the defection was proportional to the pressure in the states that the deflection was proportional to the pressure in the cylinder within the limits any particular disk was intended for. Mr. Addenbrooke thought the instrument an important improvement on its predecessors, and considered it would prove of great service to electrical engineers. Mr. Swinburne said a peculiar ment of the indicator was that it could be permanently peculiar ment of the indicator was that it could be permanently standed to an engine lite an ordonary pressure gauge. He standed to an engine lite an ordonary pressure gauge. He The President thought that the instrument could be modified to as to be useful for analyzing the shape of the curves representing alternating currents.—On Blakedey's method of measuring letternating currents.—On Blakedey's method of measuring observed in transformers, by Prof. Perry, P. R. S. Thay paper to the fact that transformers show megnetic lexiage. The proofs of the formula hatherto given have been obtained by treating the equations in the manner first adopted by Dr. Hopkinson. On this system the reactions of the primary and secondary currents in system the reactions of the primary and secondary currents. are represented by the equations-

142

$$V = R_1C_1 + P\frac{dN}{dt}, \quad o = R_1C_2 + S\frac{dN}{dt},$$

where P and N are respectively the turns on the primary and secondary coals, and N is the magnetic flux between the coals. Here it is assumed that there is no magnetic fluxes, and the author thinks that on this account the method is inferior to the original method of fluxewell, for which the modesed electromotive induction. On the assumption that there are no eddy currents, Maxwell's equations are—

 $V = R_1C_1 + L_2C_2 + MC_3 + o = R_1C_0 + MC_1 + L_2C_3$ m which although L_1 , M_1 , and L_2 may not be assumed that they are respectively proportional to P_1^2 , P_2^2 , and P_2^2 if there is no magnetic leakage p_2^2 and if the amount of magnetic leakage least contain proportion to the whole that, the three quantiles may although the samurad proportional to each other decision M_1 and M_2 is the samurad proportional to each other decisions we obtain

$$VC = R_1C_1^2 - R_2\frac{M}{L_1}C_1C_1 + \frac{L_1L_2}{L_1} - \frac{M^2}{L_1}C_1C_1.$$

Hopkinson puts down the last term as zero, but owing to the very rapid rate at which C₁ changes, the last term is very im

NO. I I 28, VOL. 44

portant, even though M may be but a small percentage less than $\sqrt{L_1 L_2}$. On integrating this equation, the first two terms on the right-hand side yield Blakesley's formula, and the last term vanishes in the integral, because, however great the magnetic issalace may be supported by the property of the property of

$$\int C_1 \dot{C}_1 dt = 0,$$

when taken over a period because the functions are periodic. The Blackeep's formula this appears to fold, whatever the magnetic leakage. The paper contains several tables of calculations showing the effect of magnetic leakage on the value of the terms in the equation. Mr. Blackeep's and he doubted the correctness of the contract of

$$X = \frac{\int x A_{\rho} \int A_{\rho} dt dt}{\epsilon + \int A_{\rho} A_{\rho} dt},$$

where A, and A, are the instantaneous values of the primary and accondary currents, and a us with that N = N(t, i + 3) where N_s and N_s are the floxes of magnetism through the primary and secondary costs at the same misstal; it is a negligibly small excluding the primary and constant of the primary and the same that it is a simple to the primary and training this factor no assumptions whatever had been made, and twas casy to see that if A, and A, could be assumed size functions, and x a constant, the value of the factor N becames a timply. In only one case did N reduce to zero, and data was amply, and the same that the constant of the constant

EGYPTIAN IRRIGATION.

THE "Note" on the above subject by Sir Colin Moncrieff, which we publish this week, will prove pleasant reading to all who have the welfare of Egypt at heart. To those who have known that country intimately in the past, the brief record of progress in irrigation since the British occupation will recall the horrors of the corude, and the torturing of the wretched neasantry by tyrannical farmers of the taxes; and to engineers the record will imply, not only that all those atrocities have been abolished, but further that some of the most difficult and important engineering problems of recent times have been successfully solved by Sir Colin Moncrieff and the able staff under his control. Nothing is exaggerated, but we have in the "Note" a plain and modest statement of the quiet and unostentatious execution of works the mere discussion of the difficulties of which had occupied the time of the predecessors of Sir Colin for the previous quarter of a century without anything useful resulting

It will be only necessary to refer to one or two matters to establish this proposition In paragraph 10, Sir Colin announces that the Barrage has been completed, and placed in a condition to fulfil its original purpose, for the sum of about £460,000 Contrast this with the published statement of M. Linant, a former engineer-in-chief of the Egyptian Government, who, in 1872, expressed a doubt whether it would not cost more to repair the existing Barrage than to build an entirely new one, and further says: " If, at the time when the Barrage was commenced, steam-engines had been what they are to-day, one would certainly have advised Mehemet Ali to abandon his project of a Barrage for the establishment of pumpingmachinery " Even at that time, M Linant thought it was not too late to consider whether it would not be better to abandon the idea of repairing the Barrage, and to assist in the determination of the question he submitted an estimate of the cost of pumping, amounting to £465,000 per annum, which, he thought, the cultivators could well afford to pay

We have already stated that Sir Colin Moncrieff has effected the same result by a single expenditure of £460,000 Instead of by an annually recurring one of £465,000. By means of the completed Barrage the whole summer supply of the Nile is thrown on to the lands, so obviously there is no work for pumps, and the vast cost of the same is saved to the country Although national feeling runs high in France, we cannot but think that French engineers will rejoice that the world-renowned Barrage of the Nile, the design of which by M. Mongel was approved of by the Council of the Ponts et Chaussées in 1842, and carried into execution during the ensuing ten years, has at last, after thirty years' practical inutility and failure, been finally completed by their worthy compeers and successors in Egypt-the British engineers-whose experience, gained in the great trugation works of our Indian Empire, has been as zealously utilized in securing the success of a great French work as it would have been in carrying out a new one of their own design.

One other matter in Sir Colin Moncrieff's " Note " may be referred to-namely, the drainage recently effected No doubt, the fact enforced upon Indian engineers by. numberless experiences-that high-level perennial irrigation must be accompanied by drainage works if soil and people are to remain in a healthy condition-was not well known to the French projectors of summer irrigation works in Egypt, and, as a consequence, whereas magnificent canals carrying 5000 cubic feet and upwards per second were constructed, no corresponding means were provided for draining the superfluous and often saline water off the lands Sir Colin tells us that the mileage of the drains at present is not less than 1500 When we consider that, in addition to these vast works of improved prigation and drainage, a steady reclamation of marshland has been going on, we have reason as a nation to be probd of the good work which our countrymen have carried on in Egypt, as, whatever may happen in the future, the fact of the British occupation will, from its successful applications of science, be indelibly stamped upon the face of the country for all time, and its memory will for other reasons live honourably in the traditions of the emancipated and much-enduring fellaheen

PHYSIOLOGICAL PSYCHOLOGY.

Leitfaden der physiologischen Psychologie. In 14 Vorlesungen Von Dr Th Ziehen, Docent in Jena (Jena: Gustav Fischer, 1891)

"HIS little volume will be welcome to a good many students of psychology, both in Germany and beyond. Anyone who has had to look up the newer researches in experimental psychology in Germany knows the serious difficulty of gaining easy access to them They are scattered over a whole heterogeneous mass of serial and other publications. Now we have to look into an avowedly psychological journal or brochure, but more frequently still into physiological works, and not infrequently into journals for psychiatry. The explanation is obvious. Psychology, in passing into the objective and experimental phase, is broadening its base to an almost perplexing extent, and is encroaching more especially on the domain of physiology. Hence the need of a volume like the present work, which aims at giving the beginner a conspectus of the psychological field. We want such a book badly in English, the only available one, that of Prof. Ladd, being at once incomplete on certain sides, and in part too metaphysical. Meantime we can recommend Dr. Ziehen's "Vorlesungen" as exceedingly well adapted to give the student a clear idea of the scope and the methods of the new science of physiological psychology.

Dr. Zieben marks off physiological from what he calls transcendental psychology by the differents that it deals with psychical processes as attached to cerebral functions. Psychophysic, the branch of investigation opened up by Weber and Fechner, he includes under physiological psychology as that part which alims at exact measurement. This seems to be a satisfactory way of mapping out the ground. The standpoint of the physiological psychologists is Indicated in the assumption that every psychical process must be thought of as having a concenniate hypological sums to place the process of the psychologists of the psychologists.

process. This, too, though it would exclude such a physiological psychology" as that of Ladd, seems a reasonable way of viewing the matter Further, the author proceeds to set forth the typical form of psychophysical process as reflex, and he considers that every known development of the psychical phase must be capable of being viewed as an incident in such a reflex process. Here Dr. Ziehen meets the real difficulty in psychology, and, as we see, meets it holdly. From the physiological point of view we are bound to take the reflex as our starting-point, and to view the most intricate plexus of cerebral processes as merely an expansion of the intermediate central stage of this reflex. But can the same mode of treatment he applied to the intricate interweavings which constitute our mental life? As mere events in time, synchronizing with neural events, they appear to be susceptible of being thus regarded, and this, as the author rightly contends, is precisely the way in which the physiological psychologist has to conceive of psychical phenomena.

146

Starting, then, with the reflex, of which the writer gives an admirable account by way of introduction, he proceeds to deal with the psychical process in its three successive stages, viz sensation, answering to the afferent or sensory section of the nervous process, ideation, or, as he puts it, association, answering to the expanded form of the central section; and action, answering to the efferent or motor section. The account of sensation is fairly full. and up to date. Perhaps the treatment of the relation of stimulus to sensation (Weber's law) is proportionately too long The discussion of the interpretation of the facts is original and interesting. The author does not like most recent physiologists, view the logarithmic ratio of stimulus to sensation as a purely physiological relation. due to what Mr James has recently called the friction of the nerve-machine, but connects it with a more general psychophysical law formulated by Hering, viz "that the purity, distinctness, or cleamess of a sensation or idea depends on the relation in which the weight of the same, ie the magnitude of the corresponding psycho-physical process, stands to the collective weight of all simultaneously present sensations and ideas, r.c. to the sum of the magnitudes of all the corresponding psycho-physical processes" At the same time the author is far from clear when he speaks of the conscious comparison of intensities as an "associative activity." This is an example of a tendency among the younger physiological psychologists to force psychical processes into a physiological framework. Comparison cannot, as Munsterberg's ingenious but futile attempts plainly show, be regarded as merely an associative process, though of course it depends on association, and in this way can be correlated with a nervous process. It must, however, be said in justice to Dr. Ziehen, that he is commendably free from the common tendency of physiologists to ignore psychical distinctions. Thus it is quite refreshing to find a physiologist contending that black and grey are positive sensations, having each its distinctive quality, like white or blue. It may be added that special interest is given to the exposition of sensation, as of the other psychical phenomena, by the frequent bringing in of the biological point of view, and the suggestion how, by the process of natural selection, particular psycho-physical

arrangements have been brought about and rendered permanent.

The account of sensation is supplemented by a chapter on the affective or emotional tone of sensations, i.e. their pleasurable or painful aspect Here, again, we have frequent references to the Darwinian theory, as when it is suggested. d propos of the fact that extreme intensities of skin-sensation, pressure, heat and cold, lose their distinctive sensational quality, and become purely affective phenomena or pains, that this arrangement has come about owing to the circumstance that in the evolution of the zoological series "intensive mechanical and caloric stimuli constitute the earliest, the most frequent, the most direct, and the greatest danger to the animal organism' (p 85) The author refers the whole of the difference in affective tone among colours, and among combinations of musical sound, to association. This seems to be going too far The contrast between the exhibitanting effect of the warm colours, and the quiet effect of those at the violet end of the spectrum, seems to be connected in part with the difference in the underlying nervous processes, and this is certainly true, as Helmholtz has shown, with respect to the emotional aspect of certain accords, eg the major and minor triads.

Coming now to the account of the idea (image and concept), we note that Dr Ziehen differs from the majority of contemporary psychologists in assigning a separate cortical element to the sensation and to the idea. These different cells (the author, in spite of Lewes's attacks on the cell-superstition, talks of the individual cell as the seat of a sensation) are closely connected, and in this way the after-effect of sensations in memory, as also the reflex effects of ideas in exciting sensations, as in hallucinations, are accounted for. The writer elaborates his peculiar anatomical hypothesis in an ingenious way. He seems to admit, however, that it is a pure hypothesis, for the facts of "mental blindness" referred to are not apparently put forward as a proof, and it may be added that rightly viewed they do not seem even to suggest the hypothesis. One may add that it appears to lack the only possible justification of such a hypothesis, viz. that it simplifies the interpretation of the facts. The other supposition, that the sensation and the idea involve the same group of central elements (not the same single cell). is more reasonable in itself, and seems to offer a readier explanation of most of the phenomena

The account of the psycho-physical process in association is less clear and instructive than most of the exposition. The author follows Munsterberg a good way at least-in reducing all association to one form, viz. contiguous, and more particularly simultaneous, association, But the diagrammatic representation of the processes strikes one as needlessly complicated by the hypothesis of separate ideational nerve-cells. Much better is the account at the close of this lecture of the way in which the different psycho-physical factors co-operate and modify one another in the actual concrete processes of reproduction. Dr. Ziehen is particularly happy in explaining the great variability of the sequences of our ideas from moment to moment. The account of the ideational stage is completed by a discussion of the relation of association to judgment and reasoning-which is a little

. 1.5

hasty, and ignores some of the main difficulties of the subject, of attention and the voluntary control of the thought-process, and of the abnormal modifications of ideation in mental disease, sleep, and hypnosis.

The unfolding of the third and final stage, voluntary action, with which the volume concludes, offers little that is noteworthy. The author adopts the new and growingly fashionable view that all our active consciousness, sense of muscular effort, and so forth, is the result of afferent nerve processes, and he proceeds, much in the manner of Munsterberg, to resolve all volitional processes into complexes of sensations and ideas, more particularly ideas of movement This seems to lead logically to the denial of any distinctive active or volitional psychosis answering to ideational or emotional psychosis, and Dr. Ziehen is not afraid to express this denial, and fortifies his position by the debatable statement that psychiatry, while acknowledging a special variety of intellectual and of emotional disturbance, knows no such thing as a distinct volitionary disturbance. It is to be added that the exposition concludes with a particularly good discussion of the final results of psycho-physical research The author here shows himself a genuine psychologist, and while insisting upon the invariable concomitance of a physiological factor in psychical phenomena, is so far from regarding the psychical as a non-essential and negligible accompaniment of the material process, that he closes in a quite Kantian strain by reminding us that the psychical chain is that which is known primarily and immediately, and which as such must always possess more reality for us

ACHIEVEMENTS IN ENGINEERING

Achievements in Engineering. By L. F. Vernon-Harcourt, M.Inst.C.E. (London: Seeley and Co, Limited, 1891.)

THE object of this book is to describe some of the principal engineering works carried out during the last fifty years at home and ahroad. The author has avoided technical phraseology to a great extent, thus making a very interesting subject as clear as may he to the general reader. Much subject-matter has been gleaned from many sources, and these are amply enumerated in the preface.

The London Metropolitan Railways and the New York elevated railways are described in chapter i growth of the Metropolitan system is very interesting, and is traced from the opening of the first section from Paddington to Farringdon Street in 1863 to the completion of the "Inner Circle" from the Mansion House to Aldgate in 1884. The author states that when the Metropolitan Railway was first designed, it was intended that the traffic should be worked by smokeless, hot-water locomotives not burning fuel, as it was supposed that the trains would be small, and that "foreign" locomotives would not travel over the line to any important extent This, however, was not carried out, and locomotives of the ordinary type were adopted. The ventilation therefore proved defective, and even to this day improvement is greatly needed in many sections. The bad atmosphere is, of course, due to the locomotives in use, and the emission of steam considerably adds to the nursance

NO. 1129, VOL. 44]

Locomotive engineering is surely able to cope with this trouble. The fead weight of the trains might be considerably reduced with advantage, and the engines designed with ample condensing arrangements, even if the latter had to be attached to the engine as a separate vehicle. The boilers should, of course, be large enough to steam well with the ordinary blower, so that all the exhaust might be condensed.

147

The Metropolitan Railway represents an engineering achievement novel in many respects and made under circumstances of peculiar difficulty On the other hand, the New York elevated railways illustrate how the American engineers solved a similar problem in a very different manner Owing to the cost of "burrowing underground," as the author aptly describes it, they resected the underground scheme, and for the same reason a railway on an arched viaduct was also considered The railways have been carried along the undesirable streets, raised above the street traffic on girders resting upon wrought iron lattice columns standing at convenient places on the line of the curb of the pavements. An illustration is given representing a street in New York and the elevated railways running on each side payment has been made for placing these columns along the streets, and no compensation has been paid for damages to residential property fronting the railways The author estimates the depreciation in value, due to the presence of the railway, as not less than 50 per cent. The cost per mile will therefore be considerably less than in the case of the London Metropolitan Railway, in which case all these items were heavily paid for. The London railway cost about £575,000 per mile, whereas the New York elevated railways only cost about £81,000 per mile.

Chapter II describes railways across the Alps, the Rocky Mountains, and the Andles. On p. 50 we find an incresting diagram representing the gradients and altitudes of the heavy portions of these lines, from which it is evident that the lines in North and South America are at higher elevations and are more subject to snow than the highest of the Alpine railways, and more severe gradients are to be found. Take, for instance, the heavy gradients are to be found Take, for instance, the heavy miles, the maximum gradient being it in 25. This portion of the line is worked by Fairlie engines, which the author attempts to describe on p. 56

The author in describing the Festiniog Railway says that the traffic is worked up the long incline by "duplex bogie engines, introduced in 1869, having two engines, united by a tender common to the two, and hinged at the centre." He goes on to say that these are called Fairlie engines, after the name of their designer. The Fairlie engines as used on the Mexican Railway certainly do not agree with this description, nor does this description agree with the usually accepted type of engine known as the "Fairlie." The Fairlie engine consists of a special type of boiler carned on bogies, one at each end These bogies have either four or six wheels, as the case may be : each bogie is fitted with steam cylinders and gear complete, and all the wheels are coupled. The boiler has a smokebox at each end, and is fitted with fire-boxes in the centre, being fired from the side. The steam pipes from the boiler to the "steam" bogies are flexible, to allow the bogies to take the curves. The water is carried in side tanks, and the fived no the top of the boller and at the side. The author will observe that there is no central pived and no tender; the engine is a take engine; and that the whole of its weight is good for adhesion. The Fairlie engines at work on the Mexican Railway weigh in order about 92 tons. The total wheel base is 32 feet 5 inches, and the raid wheel base of the boors is 8 feet 3 inches.

148

Chapter III. includes narrow gauge railways, as well as the Fell, Rigi, Pilatus, and Abt mountain railways. The use of a narrow gauge railway in place of the standard gauge is due to questions of cost of construction by diminishing the width of the line, and also enabling sharper curves to be adopted Narrow gauge railways now in use were years ago of ample capacity for the traffic then available, but are now a continual source of trouble where the traffic has increased beyond their canacity In some cases, where an increase of gauge is impossible owing to the cost, the rolling stock has to be designed to suit the abnormal requirements, and the locomotives recently designed have to be made to suit the conditions. and are working under adverse conditions from a locomotive engineer's point of view. The cost of a break of gauge is a serious matter, involving as it does the transshipment of passengers and goods, as well as two classes of rolling stock. In India, for instance, the metre gauge has given place to the broad gauge of 5 feet 6 inches in many cases, in order to obtain through communication without break of gauge The author gives an excellent description of the various mountain railways named, and they are without doubt monuments of engineering daring and skill

In chapter wan excellent description is given of the piercing of the Alps. To the ruralry of European Powers, each anxious to command a route, are due the several Alpine tunnels; from the design and execution of the Mont Cennis tunnel to the more recent schemes west of the S. Gothard. Had the author told us a bittle more about the difficulties encountered, he would have added considerably to the interest.

Tunnels under the Algs naturally give place to subsqueous tunnels in the sequence of subject-matter in the volume. The Mersey and Severn tunnels are described, and the tremendous difficulties encountered in the execution of the latter undertaking are pointed out. We also find a description of several subaqueous tunnels in the States, including the Sarma tunnel recently opened under the St. Clair river, to connect the Grand Trunk Rallway of Canada at Sarma with the United States Rallways at Port Huron. The chapter closes with an account of the proposed Channel Tunnel.

The progress and principles of modern bridge construction are treated in chapter vi. This gives a good account of the great advance made during the good account of the great advance made during the last fifty years in this important branch of engineering. Wrought-iron gradually superseded cast-iron in bridge construction, and steel has again superseded it. The manufacture of steel has now reached a stage in which there are no uncertainties in its quality. The earliest instance of the adoption of steel for a bridge is the St. Louis Bridge, over the Mississippi, constructed in 1867–74, and the most recent example is, of course, the cantilever bridge, with two spans of 1700 feet, over the Firth of

Forth The author gives the great Indian bridge over the Rom branch of the River Indian, as Stukkur, very little notice, and does scant justice to this "achievement in engineering," certainly a monument to its designer. Designed by Sir Alexander M Rendel, K.C.I.E., M Inst.C.E., and built by, and erected on the works of Messrs. Westwood, Baillie, and Co., of London, this bridge was taken to pieces and shipped to India, where it was re-erected. The chapter closes with an account of the proposed bridge over the Change over t

Submarine mining and blasting are treated in the chapter that follows. This chapter is interesting mainly owing to a detailed description of the operations for improving the entrance to New York Harbour by the removal of the obstructions at Hell Gate and Hallett's reef. With reference to the explosion at the latter site, it is interesting to observe that the earth-wave produced was carefully recorded at various places, and the rate of transmission of the shock was found to be more rapid and more uniform when the shock passed northwards through rock, than when it passed through drift in an easterly direction. In travelling through drift, it reached Goat Island, a distance of 145 miles, in 59 seconds, and Harvard College Observatory, 1823 miles, in 3 minutes 40 seconds; and in travelling through rock, it reached West Point, 424 miles distant, in 11 seconds, and Litchfield Observatory, 1741 miles away, in 451 seconds.

Chapters ix. to xv. deal with that branch of engineering which may be roughly included under the title of "Harbours and Docks." In a previous work by the author, bearing this title, and reviewed in these columns, this subject was amply dealt with, and it will now be sufficient to state that the present chapters are well up to the standard of excellence of his previous work. We find an interesting description of the Manchester Ship Canal works in these chapters-a work rapidly nearing completion, and one which, if successful, will be the forerunner of many similar works in this country An illustration is given, showing the progress of the works forming the Eastham Locks, viewed from the Eastham end. This illustration gives a very good idea of the magnitude of the undertaking. Another Manchester undertaking occupies considerable space in this work, viz. the Manchester waterworks, and more particularly the Thirlmere scheme. The author tells us that the eventual maximum daily supply of 50 million gallons of water will be conveyed to Manchester by an aqueduct, or conduit, about 100 miles long. Another similar undertaking is also discussed; in the Liverpool Vyrnwy scheme we find how engineers have solved the difficulty of getting a pure water supply for that city,

The volume concludes with an account of the Eddystone Lighthouse and the Eiffel Tower.

The frontispiece is a portrait of Robert Stephenson, a way appropriate one for such a work. His name will ever be associated with the development of railways, as the author remarks, and he might also have pointed out that the railway has been in many cases the reason for many "achievements in engineering" being called into existence.

Taken as a whole, this work is a very interesting one. It is well written, and the author may be congratulated on having succeeded in his endeavour to describe briefly some of the principal engineering works carried out, at home and abroad, within the last fifty years. The book is well printed, and the illustrations are excellent, although there might perhaps have been more of them, considering that the general reader has to be provided for.

GEOLOGICAL EXCURSIONS.

Geologists' Association: a Record of Excursions made between 1860 and 1890. Edited by Thomas Vincent Holmes, F.G.S., and C. Davies Sherborn, F.G.S. (London: E. Stanford, 1801.)

THE Geologists' Association began its useful career of work more than thirty years since. It has stimulated-more, perhaps, than any other body-a real interest in geology among those who live in and about London, because it has enabled students, still near the outset of their work, not only to meet for mutual help and encouragement, but also to be aided by those of repute in science Of its meetings, not the least pleasant and useful are the excursions. At first these were made generally once a week, so long as weather permitted, and they occurred a Saturday afternoon or at most a single day. Then an occasional journey of longer duration was attempted : now it is usual to undertake excursions, lasting two or three days, at Easter and Whitsuntide, and one of a week or more during the summer holidays Before each excursion a flysheet is issued to the members with a brief description of the geology of the locality, illustrated by diagrams and containing references to books and papers Afterwards, a report of the excursion is inserted in the Proceedings of the Association It was a happy thought to collect together in one volume these scattered notices, for they give succinct descriptions of almost all the localities of geological interest readily reached from London, so grouped as to be conveniently accessible. Thus the student, instead of having to compile for himself, from books or maps, a plan of campaign. whether for an afternoon or for a longer time, finds everything arranged ready to his hand, and is directed to the sections best worth visiting. These diagrams and reports possess a further value, that they frequently record sections which can be no longer examined, because they now either are overgrown by vegetation, or have been removed in quarrying The work therefore is a geological guide-book of an exceptional and a very convenient character to a large district around London, and to several other localities of special interest in England.

The plan which has been followed in compiling the volume is stated in the preface. The excursions are grouped, as far as possible, within county boundaries, where more than one use has been pard to any place, the editors have "either suppressed the shorter, and retained the foller, or given from each account that which is not to be found clawshere." The reports have been condensed by the excussion of matters of general or merely temporary interest, and although references are made to all excursions up to the year 1890, no reports are given of later dates than 1884, because since 1883 it has been customary to print all these in the November number of the Proceedings, so that they can be easily consulted

NO. 1129, VOL. 44

The thanks of the Association-indeed of a wider circle of geologists-are due to the editors for the pains which they have taken in discharging a very laborious duty It seems almost ungracious to criticize, and to do it effectively would require encyclopædic knowledge; but we think that, though it may have been "impossible to send each report to the original reporter for revision," it would have been prudent to submit it to someone with a special knowledge of each district. These reports occasionally contain obiter dicta, or the crude speculations of members who are better acquainted with their own locality than with the principles of the science Hence obsolete notions are preserved like flies in amber: these may perplex, but they cannot help the beginner. By way of testing the results of the editors' method, we have examined the reports of two or three districts with which we are specially familiar. The statement on p 203 about the section at Roswell Pit, near Ely, is misleading The natural interpretation of its words would be that the Kimeridge clay formed a part of the great erratic This, in reality, consists of Cretaceous rocks, the Jurassic clay being in situ. On p. 216, the sentence "at the base, as at the top of the Gault," should have been "below the base, as above the top." Again, the clay beneath the neighbouring Upware limestone, now admitted to be Coral rag, cannot well be Ampthill clay, and we are not aware of any evidence in favour of this view Again, the account of Charnwood Forest needs correction At p 463 a statement is quoted, which was published without due authority, and has been recalled by the author. On pp 465 and 466 the suggestion that the Charnwood Forest rocks "ought to be called Laurentian" should have been cancelled. It was groundkss, even as Laurentian was defined in 1875 it is absurd now All reference to the "Archæan Petrology" of Prof. Ansted might well have been omitted On p 472, Peldar Tor is twice misprinted Peddar Tor We know of no ground for the statement, on p 473, that "the quartz [m the rocks of this neighbourhood] appears to be of subsequent formation," Doubtless similar defects could be pointed out by others : indeed, our own list is not quite exhausted, but we have no desire to carp at a book on which so much labour has been bestowed, and prefer to welcome it as a valuable addition to British geology, which will be indispensable to all students who live in the neighbourhood of the metropolis T. G B

OUR BOOK SHELF.

Across East African Glaciers: An Account of the First Ascent of Kitmanyaro By Dr Hans Meyer Translated from the German by E. H. S. Calder. (London: George Philip and Son, 1801)

LON. before he thought of exploring any part of Africa. Dr. Meyer was an experienced and exhimisative traveller. The idea of undertaking explorations in "the Dark Connent" was suggested to him by the fact that while the German colonial possessions in the west of Africa had been thoroughly investigated under Government supervision, and at the Government expense, those in the East had been left to the more limited resources of commercial companies. It occurred to Dr. Meyer that himself to the task which the German Government seemed so uswilling to undertake Accordingly, in 1886, he began to make preparations for the accomplishment of his plan

and since that time he has organized no fewer than three important expeditions, in the third of which he succeeded in reaching the top of Kilimanjaro. It is this third expedition of which an account is given in the present work. The broad results of the journey were soon made known : but of course it is only from th explorer's full narrative that an adequate idea can be formed of the interest and importance of his achieve-ments. The mountain mass of Kilimanjaro towers up to a height of nearly 20,000 feet, and Dr. Meyer describes well the feelings with which he saw it after his arduous march across the steppes "It was a picture," he says, "full of contrasts-here the swelling heat of the equator, the naked negro, and the palm-trees of Taveta—yonder, arctic snow and ice, and an atmosphere of god-like rearcue snow and ice, and an atmosphere of god-like re-pose, where once was the angry turmoil of a fiery volcano." The story of the ascent is told most vividly, and there are few readers who will not sympathize with the delight with which he speaks of the moment when he set foot on the culminating peak Although the record of his ex-periences at Kilimanjaro forms the centre of the book, he has much to say about what he saw both on his way to the mountain and on his way back; and in appendices various writers present classifications of his collections, and the conclusions at which they have arrived in working out his astronomical and meteorological data. The book is admirably translated, and its value is greatly increased by illustrations and maps.

Chemistry in Space From Prof T H van 't Hoff's "Dix Années dans l'Histoire d'une Théone" Translated and Edited by J. E. Marsh, B.A. (Oxford: Claren-don Fress, 1891.)

WE have already reviewed the monograph of which this is a translation (NATURE, vol xxxvii. p. 121), and need not therefore, at present, say anything of the subject with which it deals. The translator has done his work carewhich it death. The maintain has done his work card-fully, and "the invaluable assistance and advice" of the author have enabled him to make his rendering "a con-siderable extension of the French edition" Mr Marsh advises those to whom the question is new to leave the first chapter till the end, as it contains a translation of the earliest memoirs on the subject, and the ideas are incompletely developed, obscure, and sometimes erroncous.

LETTERS TO THE EDITOR.

Erratic Track of a Barometric Depression.

Erratic Track of a Barometric Depression.

This angular course of the cycloid system which has, during the wesk terminating on May 29, circulated round and across the British Islee, deserves more attention than can be thus early green to it. I with here, with your permission, first, to describe the path fits centre as correctly as can be done with the principal modifications of the stohars and of the weather in the neighborhood of the centre; secondly, to mention some remarkable facts in relation to the upper currents as observed by mayelf in its neighborhood; and finally, to indicate the believe, in the instance before mis, prove to be of most scientific value.

value. (1) The accompanying chart shows the course of the centre of depression, so far as we have yet been able to follow its track; the arrow-beads marking the position at 6 p n., of each day. At 8 a.m. of the 2yrd, the centre appears to have also about the matter of the war of Erris Head, with a baron-day pressure of a little before 2y2. By 6 p.m. it had defined the contraction of the con

English miles per hour, and by 8 a.m. of the sath to a little west of St. Anne's Head. During the above period the depression was clongaring listle, the position of its major axis changing from N.W.-S into W.-E. The weather in the meantime was made to the state of ward, having moved during lie twenty-four hors with a velocity of 10 miles per hour. By the moning of the 26th the centre was near the mouth of the Humber, nainfall continuing over the mouther of the period of the centre of th circular in form, and the central pressures slightly decreasing. During this day rain and cloud prevailed on the west of the system, while in its rear there were some scattered thunder and hall

showers of the type prevalent in summer in the rear of cyclonic systems travelling to nonth-east. At 6 p.m. on the following systems travelling to be shown that the system of the system had almost left our shores, finer weather setting in over Great almost left our over Great system had Britain generally.

(2) The point marked with an asterisk on the chart marks

An of the position of the propers of the depression, a position of vanings for the observation of upper current, the water during the progress of the depression, a position of vanings for the observation of upper current, the value of which was much dimminded by the precluminant thick-own of the propersion of the pro

evening, which showed that the upper current had changed to south-east. No observations could be made during the two wet days which followed; but early in the morning of the 27th, when the centre was about 100 miles to the north, true cirri were the centre was about 100 miles to the norm, true crit were observed moving slowly from north-east. These soon disap-peared; but at 6 p.m of the same day an important change took place, the bands of ice cloud moving from south-south-west, from which point, or from a little west of it, the belts have continued to travel up to the time of my writing this, the lines being nearly parallel to the isobars, and to the general direction of the surface winds, and precisely resembling in character the stripes depression, whose centre has passed a little to the north of the

observer, has moved away to north-east.¹
(3) In an dishortse paper in the Quant. Journ of the R.
Met. Soc for October 1877, the writer pounted out than in the mount of the part of the state in the upper that in the lower state of the atmosphere in the regions traversed by extra-tropical cyclones. Over a large number of these cyclones, therefore, many of the isobars in the upper regions of the atmosphere do not form closed curves, but upper regions of the atmosphere do not form closed curves, but curves somewhat resembling those which, at the earth's surface, accompanying what are popularly termed V-shaped depressions it is a question of the utmost interest whether, daming the periods in which depressions irrivel to the west, the distribution of gradients in the upper atmosphere is really for the time reversed, and, if so, what can be the causes of so remarkable a change. There is a further question correlated with the above, which deserves more attention than has been given to it. The writer deserves more attention than has been given to it. The writter too gag oppointed out (Joann Scot Met Soc, vol iv pp 333-335) that in cases of depressions travelling wetward across our stands, temperatures at the earth's surface are in general higher of lintances have occurred since 1875 which have confirmed that conclusion. But in most of these cesses an anticipolons has lain to the north seat of us, so that the "gradient force" of the most of the surface of the surf ton addition to the ascensional force, associated with condensa tion in the western segment, due to the indraught of relatively warm air from north and north-east. In the instance described warm air from north and north-east. In the instance descrines in this paper pressure was not particularly high over Scandinavia, during the westward progress of the system, but temperature seems to have been higher, over Sweden at leas', than France.

The Crowing of the Jungle Cock

IN NATURE (vol. xhii p 295) Mi Henry O Forbes has a letter commenting on a statement of Mr Bartlen to the effect letter commensing on a statement of Mr. Barden to the effect that the wild applie cock does not crow, and tearinging that he once heard one. In reply, in the next number of NA1URA, if a concept the control of the control of the control of the All Table 1. If thick that no one who has traveled in the jungle of Barna, during the dry season, can have any doubt that the jungle cock overs, for he cannot fail to have been't them many mer. I had occasion to travel among the hills which form the waterched between the Irawaddy and the Stoting rivers. I non region here a large kind of bamboo was seeding, so that the jungle mabers. I remember one place to particular: the Katen had

numbers. I remember one place in particular . the Karens had prepared us a hut in which to sleep just outside of their village, which consisted, like nearly all the villages in these hills, of a single house, each family having its separate room in the common

"These stopps or currictions are so abundant in the case of most de-pressions, towers the termination of the numerion distributions accompany-ing squalts or thunder showers in Europe and the Northern States that it is augusticly understants that the statement of an English mectorologist, to the augustic production of the statement of the statement of the statement of Ferrel's "Popular Treatise on the Winds" it way into the first edition of Ferrel's "Popular Treatise on the Winds", it to, "Modern Mescoology," p 111

building. "At cock crowing" in the morning we had, close to us, the crowing of the village cocks, and on every side, far and near, the answering crows of multitudes of wild birds. I do no remember ever to have been treated to such a chanticleer concert

The idea that these wild cocks were all hybrids is inadmissible. because (I) they were so very numerous, and (2) the country is very sparsely peopled, the villages all being small and far apart, and the greater part of the country still covered with primæval

The crow of the jungle cock is shrill, like that of the smallest breeds of domestic fowl, and is, perhaps, a little less prolonged than that of the average domestic cock; but it can hardly be distinguished from the crow of a small breed of fowl kept by the Karens, some individuals of which so closely resemble the wild fowl that they are used as decovs.

sows ust they are used as decoys.

I have several times heard wild fowl cackle, and in this poursey, while in the molet of a heavy forest, miles from any human habitation, we came upon a flock of wild fool eacking, and could tell by the tones that both cocks and hens were each long. One of the followers being sent with a gue to it y and get a vitor, some of the briefs was him and flew, whereupon one of the cocking was the peculiar call which the domentic cock gives

when a bird flies over him I might add that, among the numerous birds shot in this region, there was one hen which had a pair of spurs about half an inch long
Rangoon, May 20

Cordylophora lacustris.

It is generally believed that this tube-dwelling Hydrozoa was originally a sait water animal, and although now found a con-siderable distance from tidal water, it still dwells in rivers and canals more or less connected with tidal rivers. I have for many years found it in the Chester and Ellesmere Port Canal. many years tound it in the Chester and Elemere Fort Cana, growing principally on the shell, of the fresh-water mussel, from two to three miles from the tidal river (the Dee). It seems to be a shade-loving animal, at I have always found it under the bridges, and from 4 to 6 feet ben ath the surface of the water.

The tubes only remain during the winter and early spring, and the animal is fully developed in August and September. It is generally accompanied by Fredericella sultana.

THOMAS SHEPHEARD.

Kingsley Lodge, Chester, June 12

Philosophical Instrument Makers,

I FIND in your paper of fune II (p 135) that Messrs. Newton I FIND in your paper of tune it (p. 133) that Messirs. Newton and Co have been appointed philo-ophical instrument makers to the Royal Institution of Great Britain. Allow me to state that they are not the only ones, and that I also was appointed on Jane t by the managers of the Royal Institution of Great Britain to be their philo-ophical instraument maker. I thought that in the interest of the public you should know this fact, A. HILGER.

NOTE ON EGYPTIAN IRRIGATION.

N entering upon any account of Egyptian irrigation it is necessary, at first, to point out that it consists of two very broad subdivisions. (1) the irrigation effected by the Nile flood when there is rich muddy water in abundance for a land thrice as big as Egypt, and when everyone considers it his absolute right to have his fields flooded without the expense or trouble of raising the water artificially; and (2) the irrigation effected by the Nile at its lowest, in those hot months of May and June when the water surface is 20 feet below that of the field, and when it is only by the strictest economy that we can water an area not exceeding one-fourth of the whole of

2 The Irrigation of Old Egypt —The first irrigation is the ancient art of Egypt, the culture that, from the days of the Pharaohs, made this little valley the granary of Europe. The products are wheat, baries, beans, maize, and rice. These two last crops require special irrigation. For the gro vith of wheat, barley, and beans, it is enough to saturate the fields, during high flood, from August to October The seed is scattered as the waters retreat, and the fields receive neither irrigation nor rain from that time till the harvest is gathered in at the end of April

3. Perennial Irrigation .- The introduction of the second system is due to the sagacity of Mohamed Ali, who saw that the conditions of soil and climate were such as to favour the growth of cotton and sugar-cane, sub-tropical products greatly exceeding the value of cereals these crops require irrigation during the months when the Nile is at its lowest, hence a system of deep canals was necessary, and it was in trying to carry out this system in Lower Egypt that the Egyptians got into hopeless difficulties, for the canals got blocked with silt, and

it was most difficult to clear them.

152

4 The Barrage unused — The obvious remedy was to raise the water in the river, and divert it into the canals hy a Barrage or dam at the apex of the Delta Such a work was constructed, at a cost of about two millions sterling; but soon after its completion it cracked in a stering; out soon after its confection it cracked in wery alarming way, and, from 1867 to 1883, remained practically useless. The great network of canals continued to be cleared year after year to a depth of about 20 feet below the soil, and for half of each year the corvole

was constantly employed on them.

5 Pumping—The Egyptian Government had abandoned all hope of again using the Barrage. They had entered into a contract with a private company to irrigate Behera by a system of pumps, at an annual cost of from £50,000 to £60,000; and they were about to come to similar arrangements for the rest of the Delta, at an

initial cost of £700,000, and an annual one of £250,000

6 Neglect of Drainage —Continuous irrigation like that of Lower Egypt requires to be accompanied by drainage, otherwise the land becomes soured and waterlogged. No

attention was being paid to this subject in 1883
7. State of Upper Frypt — The first system of irrigation alluded to above continued to be practised in Upper Egypt A few very costly bridges had been built to assist it, but little attention was being bestowed on it, and even in years of average Nile flood we found a loss of annual revenue amounting to about £38,000 taking

8 Addition to Area of Egypt -Such was the state of affairs when we took charge of the irrigation in 1884. am frequently asked whether, since then, there has not been a great addition to the cultivated area of Egypt.

My reply is in the negative.

The question of extending cultivation into the desert is partly one of displacement of population, chiefly one of level, for above the point that the Nile flood can be brought to reach we must not look for an extension of cultivation. Some goes on-notably to the west of the province of Behera and in the Fayoum; but it is not on a very large scale.

o Reclamation of Marshes -An extension much more rapid, and of more importance, is in progress along all the north of the Delta, where land is being yearly reclaimed from marsh and lagoon by our drainage operations.

The cultivated and revenue-paying area of Egypt is about five millions of acres. The lagoons in the north cover an area of about 1,280,000 acres. I expect in a very few years to see at least half of this land reclaimed and cultivated.

10. The Barrage repaired, and the Effect on Lower

10. The Harrage reputred, and the Light of Sept.—What we have done, are dong, and propose to do, then, in future years is as follows:—

First. The Barrage has been completed, and placed in a condition to fulfil its original purpose. From the stream of it are derived three main trunk canals which irrigate the whole Delta, and three smaller canals which irrigate all the country north-east of Cairo and to the south of Zagazig, one of these takes water to Port Said and Suez. The outlay on the Barrage has been, since

1884, about £460,000. Of the three trunk canals, that on the west had been neglected, and completely filled in with sand. It has been restored, and the system of pumps alluded to in paragraph 5 will, I hope, never be used again,

The canal supplying the East Delta (termed the Tewfikieh Canal) has been entirely made since 1886, at a cost

of £372,000

Practically, the whole summer supply of the Nile is diverted by the Barrage into these canals, and none flows The value of the work is thisout useless to the sea that so long as there is water in the Nile it is under our control, and, however low the river may fall, the water will get on to the fields, and the great cotton crop will be secured In former days, during low Nile, the canals were left high and dry, and what water there was flowed out to the sea, useless.

The Barrage has not much increased the area of cultivation, but it has very largely increased that of land bearing double crops—that is, the area producing cotton bearing double crops—that is, the area producing conton It was in 1884 that, by employing temporary measures, we began to use the Barrage—Since then, the average annual yield of cotton has been 333,893 kantars (12,000 tons) greater than in the five years preceding 1884.—This tons) greater than in the five years preceding 1884. represents a value to the country of £835,000 a year, exclusive of the value of cotton-seeds

11 Provision for Navigation - Secondly As the abstraction of water renders impossible the river navigation straction of water renders impossible the river having and durling four or five months every year, two main canals have been selected, one of them roughly parallel to each of the branches of the Nile, and fitted with locks and rendered navigable. This is not yet quite finished. When it is, it will enable laden boats to pass freely be tween Cairo and Alexandria on one side, and Cairo and Damietta on the other side, at all seasons of the year Other locks have been built, and obstructions removed, so that navigation has had an impulse given to it throughout the whole Delta.

12 Drainage Introduced .- Thirdly. Year by year have been opened out new miles of drainage arteries, and in Behera, Gharbieh, Dakahlieh, Sharkieh in Lower Egypt, and in the Fayoum, large tracts have been reclaim from salt-marsh, and now yield good crops. The Budget for the current year contains £140,000 for new drainageworks in Lower Egypt No part of our work has been more appreciated than this, but, unfortunately, the defective system of revenue statistics makes it impossible to say what lands have been reclaimed. The mileage of drains is not less than 1500

13 Measures for Improving Irrigation of Upper Egypt — Fourthly. 1 have said, in paragraph 7, that there has been an annual loss of about 438,000 in average there has been an annual 1050 rabout 3.50.00 inaverage years, due to the Nile flood not attaining all the fields of Upper Egypt In exceptional years this loss has been much greater. Thus, after the very deficient flood of 1877 it amounted to £1,111,880. After 1888 it was about £300,000. If such was the loss of revenue alone, it may ue imagined what a heavy calamity was inflicted on the

cultivators. Colonel Ross, Inspector-General of Irrigathese deficient years there was water enough in the river that, by a judicious system of canals, sluices, siphons, escapes, weirs, &c, it may be arranged that, even in the worst years, the whole Nile valley shall receive its share of mud-charged water

This involves the construction of no great work like the Barrage (the most expensive does not exceed £45,000), but of a great number of works costing from £5000 to £15,000 each, requiring very careful designing, and built often in remote spots, where construction of any kind is difficult.

construction of any sind is diment.
These works have been going on now for more than a vear. When finished, as I hope they will be in 1893, the whole outlay will be about £600,000. And then, I crust, the lands of Upper Egypt will yield their full crop, however defective may be the Nike Bood
14. Agricultural Koad—Fifthly. A minor subject,

and yet one of great value to the country, deserves notice here—namely, the introduction of agricultural roads, This reform is due to Riaz Pasha Until two years ago at would have been impossible to take a cart-load of agricultural produce from any one centre of population to another in the Delta. Comparatively few of the canals were adapted for boats, and the one means of transporting cotton to the railway stations or to the river was by ing cotton to the railway stations or to the river way camels, which, however well adapted for carrying burdens on the firm sand of the desert, are not suitable for the rich alluvial soil and the sloppy fields of the Nile valley This is all being changed. The people have willingly accepted a tax never exceeding P.E. 4 or 5 per feddan for one year only, and, with the fund thus raised, a whole network of serviceable roads is being formed sufficiently adapted for this dry climate

15. Corvée Abolition - The above paragraphs describe generally the improvements that have been brought about in the last seven years Second to none is the boon that has been conferred on Egypt in the abolition of the in the clearance and repairs of canals and embankments was effected by the forced, unpaid, unfed labour of the peasantry. In 1884 this labour amounted to 85,000 men working for 160 days. We were told that this was quite a necessary state of things, that it would be impossible to maintain the irrigation-works otherwise, and that the Egyptian peasant, unlike that of any other country, would not work for wages, and must be forced We estimated that to redeem this corvée and to pay for all this labour would cost £400,000 Nubar Pasha, in the face of the greatest financial difficulty and opposition, managed to give an annual grant of £250,000 for this object. Riaz Pasha, at the end of 1889, found means of granting the remaining £150,000, and in 1890, for the first time per-haps in all history, there was no corvée in Egypt

16. Canal Legislation - When we began work here, we were much hampered by the want of any canal legisfation, there being no law corresponding to what is found in India, Italy, and elsewhere, treating of the many con-flicting questions connected with irrigation. After three years' discussion, a very useful Canal Act now exists, and the only misfortune is that it is not binding on residents

of foreign nationality.

17 Storage of Nile Water - Lastly, as regards our programme for the future, there is abundance to do in carrying out, year by year, solid unpretending reforms; but, besides these, a very large question is coming to the front. The restoration of the Barrage placed at our disposal all the water of low Nile, but the increase in the area irrigated outruns the increase in the water available, and we have to look for means of storing the surplus volume of the flood, and utilizing it when the river is low.

There are two ways in which this may probably be done. The first, which is connected with the name of an

ingenious American gentleman, Mr. Cope Whitehouse, is to divert a portion of the flood into a great natural depression existing west of the Nile valley, and there to form a storage reservoir, to be drawn upon as the water in the river decreases. This has been examined and found feasible, but the expense, probably 18 millions sterling, is against it The alternative project is to pond up water in the valley of the river itself above Assouan This project is being studied at present There can be hardly any further extension of the cotton cultivation if one or the other of these schemes is not executed. There

is room enough in the country to employ both.

COLIN SCOTI MONCRIEFF,

Under-Secretary of State, Public Works Department

Cairo, March 5, 1891.

THE SECOND ORNITHOLOGICAL CONGRESS.

A FULL report of the proceedings of this important Congress can only be obtained when the official Comptes rendus are published, for the officers of one section were unable to attend the meetings of the other sections owing to the fact that all four sections sat at one and the same time. This is the only complaint we have to make concerning the recent proceedings, but as it affects the future of these useful reumons, we feel compelled to make our protest, because, by the simultaneous session of all the sections of a Congress, no man, however interested in the subjects under discussion, can hear all that he wishes to hear, the visitor has to choose between two meetings, both of which probably possess for him an equal interest It must be obvious to everyone who had the privilege of attending the second Ornithological Congress that a great gathering of specialists such as that which took place last month must require more time than three days to discuss such varied problems as were placed

The city of Budapest was happily chosen as the meeting-place of the Congress, and it may well be questioned whether there is any country in the world that could have offered so many attractions to the ornithologist as Hungary The hospitality of the Hungarians is proverbial, the accommodation in the beautiful capital is unlimited, and access thereto is easy. After an enjoyable trip down the Danube from Vienna, the travellers found themselves at the opening conversations of the Congress, which was celebrated in the Grand Hotel "Hungaria." Here the Hungarian Committee had assembled with all the members of the Congress to welcome the guests, and the inaugural banquet served as a pleasant medium for the introduction of the strangers On May 17 the first general meeting of the Congress took place in the sumptuous theatre of the Hungarian National Museum After some words of welcome from the Burgomaster of Budapest, the officers for the Congress were chosen as follows:—Honorary Presidents Count Bethlen, Minister of Agriculture; Count A. Csáky, Minister of Public In-struction; Mr B Kállay, Minister of Finance Presidents Prof. Victor Fatio (Geneva) and Mr. Otto Herman, M.P. Vice-Presidents: Dr Rudolph Blasius (Brunswick), Prof. S Brusina (Agram), Prof. R Collett (Christiania), Mr. J S Brusina (Agram), Prot. A Conett (Streen), Major de Csató (Budapest), Dr. Otto Finsch (Bremen), Major (Bremen Alex von Honieger (Greifswald), Dr A B. Meyer (Dresden), Dr. E. von Middendorf (Livonia), Dr. Enst Oustalet (Paris), Dr. Bowdler Sharpe (British Museum), Mr. E von Szalay (Budapest), Victor Ritter Tschusi von Mr. E. Von Szaiay, (totagest), victor atter Isanisi von Schmidhoffen (Hallein). General Secretary Dr. G. von Horvath. Secretaries: Mr. E. Chernel von Chemel-haza, Dr. A. Lendl, Dr. L. Lorenz von Liburnau, Dr. A. Lovassy, Dr. J. von Madarása, Mr. O. Reiser, Prof. G. Szikla. Hon Secretaries: Mr. E. de Gadl, Mr. Prof. G Szikia. Hon Secretaries: Mr. E. de Gaal, Mr. B. de Lipthay, Mr. J. d'Ottlik. Quæstor. Mr. J. von

Xántus. After preliminary reports, Major Alex. von Homever gave his reminiscences of travel in West Africa. some years ago, and his imitations of the notes of African birds were strikingly rendered. Four different sections of the Congress were appointed, the names of the different delegates from foreign countries were read out, as well as letters of apology for their absence from several naturalists. Prof. Furbringer, Baron de Selys Longchamps, and others.

The officers of the different sections were constituted as The officers of the different sections were constituted as follows:—(1) Systematic Section, Presidents, Dr. Bowdler Sharpe (London) and Prof Class (Petinna); Vice-Presidents, Dr. A Rechemow (Erdina) and Mr. C. Danfordon, Dr. A Rechemow (Erdina) and Mr. C. Danfordon, Dr. Alberton, D

a view not to be surpassed in beauty and interest in any

a view not to be surpassed in beauty and interest in any country.

On Monday, May 18, the Systematic Section met in the lecture-theatre of the Polytechnicum, which was placed at the disposal of the Congress by Prof. Stabo, whose work is well known and appreciated in Grest Britain. Papers were read by Prof. Klug, on some points in the announy of the stomach in brids, and by Dr. Bowdler Sharpe on the classification of birds. by Dr. Bowdler Sharpe on the classification of birds, the latter lecture being illustrated by several large diagrams and a wax model of the phylogenetic tree, in which Prof. Furbringer traces the evolution of birds from a reptilian stock. The remainder of the work of the systematic Section consisted in the passing of the rules of nomenclature, as put forward by a committee consist-ing of Prof. Mobius, Dr. A. Reichenow, Count von Berle-poch, Dr. A. B. Meyer, and Dr. W. Blasius. The recommendations of this committee were adopted, almost in their entirety by the meeting, after a two-days' discussion, notwithstanding some protests of Dr Sharpe, and Mr. Buttikofer of the Royal Museum of Leyden, who found themselves in a hopeless minority. The chief points carried were: the adoption of the 10th instead of the 12th edition of the "Systema Nature" of Linneus, the recognition of trinomial names in certain cases, and the adoption of names, even faulty in construction or misspelt, with all the consequences The tone of the report, however, is so moderate, and exhibits so much consideration for the methods of other ornithologists, that it ought to be possible now to arrive at a definite conclusion for European usage at least, and then it would be easy to assimilate the American and European methods of nomenclature.

In the afternoon of the 18th, the Congress met in the Museum, and Dr Otto Herman, M P., gave an account of the distribution of birds in Hungary, and explained the collections which had been made specially for the Congress These consisted of beautifully mounted cases of Hungarian birds with nests and natural surroundings. some very rare species were included in the collection, which was the work of four ornithologists-Dr O Herman, which was the work of four ornithologists—LT O TERMEN, M P, DT Julius von Madarást, Mr. Chernel, and Prof Szikia. These gentlemen had each occupied a station in different parts of Hungary, and had not only collected the series of biids exhibited, but had also made exact the series of builds exhibited, but had also made exact observations on migration and distribution. The Hungarian National Museum is a very fine building, and contains a collection which fairly surprised most of the visitors, the series of native birds being especially complete. Large groups of Laemmergeners, Sea Eagles, Ospiery, &c., with their nests, eggs, and young birds, are to be seen in the Bird-galleries, and these are principally the work of a well-known Hungarian ornithologist, Dr J von Madarász. The collection of Mammalia also com-

prises some great rarntes, and the whole Museum teems with specimens procured by the veteran explorer, Mr. J. von Xántus, whose labours in Lower California and Central America, as well as in Borneo and the Sunda Islands, are also widely known. The Museum likewise contains a fine series of insects, especially likewise contains a nne series of insects, especiasing Coleoptera, which were shown with much natural pride by Dr. Frivaldsky, who is responsible for the leautiful arrangement of the latter groups. The afternoon closed with an adjournment to the Hungarian Academy of Sciences, where Prof. Robert Collett read a paper on Arctic Bird-life before a crowded audience, and the evening concluded with a banquet at the "Archiduc Stephan" Hotel.

On Tuesday the debate on nomenclature was continued; and in the afternoon the Congress assembled on St. Margaret's Island, which forms a most delightful summer retreat for the inhabitants of Budapest, with its dozens of nightingales, its ruined cloisters, and its sulpbur

On Wednesday, the 20th, the general meeting of the Congress was held to receive the reports of the different sections and committees, and the business was concluded. A farewell banquet took place in the evening, and the second Ornithological Congress came to an end

Next day the members were scattered in different directions—some to their homes, some to join one of the pre-arranged excursions. These were three in number— one to the Hanság marshes and Ferto, a second to the Platten-See, and a third to the districts of the Drave. Of the first excursion, in which the writer took part, he can only say that, under the direction of Dr von Madarász, the members of the Congress who accompanied it underwent a never-to-be-forgotten experience The species of birds observed were mostly those unknown to an English naturalist, and the hospitality dispensed by Prince Esterhary, Baron von Berg, and Count Széchenyi, is not likely to disappear from the memory of those who had the good fortune to partake of it.

THE IMPERIAL PHYSICAL AND TECHNICAL
INSTITUTION AT BERLIN.

THE Imperial Physical and Technical Institution which was founded in 1887 at Charlottenburg, near Berlin, under the auspices of the German Government, has now been for some time in active operation, and recently there has been issued by the executive Director. Dr. L. Loewenherr, a Report on the work of the Institution up to the end of last year.

It may be remembered that the Institution has two main objects in view. first, that of physical and technical research appropriate to the practical development of manufacture-researches for instance as to the qualities of metals and materials and as to methods of construction and measurement; the second object being that of fundamental research in theoretical problems in physics, and the testing of all kinds of measuring apparatus applicable for use in science, art, and manufacture. It appears to undertake, therefore, investigations and verifications similar to those undertaken in this country by the Board of Trade, or at the Kew Observatory . and, in France, by the Bureau International des Poids et Mesures. Its staff includes (exclusive of the clerical staff) a President, nominated by the Reichstag, a Director, with a Committee of seven members; seven scientific officers in the department of research; four technical assistants, and several mechanics and machinists

From time to time, as new methods of testing are adopted, or as fresh work is undertaken, explanatory papers are issued by the responsible officers of the Instimeteorological measurements; Dr. K. Feussner and Dr St. Lindeck, on electrical measurements; Dr. O. Lummer and Dr. E. Brodhun, on optical measurements, including photometry; Dr. F. Foerster and Dr. F. Milius, on chemical analysis of glass.

We gather from the Director's Report above referred to, that the Institution has provided itself with funda-mental standards of length and mass: with primary thermometers and barometers; with electrical standards of resistance, current, and pressure; and with apparatus for testing the flashing point of petroleum and inflammable liquids. Its metrological work for the public has included the proving of clinical thermometers, pyrometers, aneroid barometers, manometers, alcohol thermometers for low temperature, and thermometers for chemical research.

In October 1888, the official testing of thermometers was transferred from the Normal Alchungs Commission at Berlin to the Imperial Institution, and all thermometers are still tested on the basis of the regulations laid down by the Commission on November 10, 1885; excepting that, in place of basing the errors of scientific thermometers on a mercurial thermometer, thermometer readings

are now reduced to the more accurate scale of the airthermometer or hydrogen-thermometer.

The use of thermometers for determining pressures, or altitudes, &c., on the occasion of journeys of exploration, &c., seems of late to have increased, for many such have act, seems of rate to nave increased, for many such have been already presented for examination at the Institu-tion If the thermometers are made of Jena glass (or of other hard thermometer glass), it would appear to be possible to ascertain pressures with but little trouble to ± 0.23 millimetre The necessity for using proper glass is shown in an experiment carried out at the Institution with two thermometers, Nos. 42 and 43, made of ordinary Thuringian and crystal glass. On September 7, 1888, the corrections of these thermometers at 87° C. were found to be-

The thermometers were then heated for 15 minutes to a temperature of 100° C; they were then allowed to cool, and subsequently retested on September 10, when their errors were found to be-

Such variation in the reading of a thermometer after its exposure to a high temperature would unfit it for use in the exact determination of pressures or altitudes

With reference to the testing of various sorts of glass Dr. F. Milius points out that Weber's process, generally made use of, and which consists in exposing the body to be examined to an atmosphere of muriatic acid vapour for a space of twenty-four hours, is not always trustworthy Thus, according to the quality of the glass, it appears to be covered more or less, after exposure to the acid vapour, by a thick rime (or hoar frost), and that although the exa thick rime (or noar trost), and that although the ex-perienced observer finds Weber's method tolerably certain, yet the less experienced observer may sometimes be left in doubt, particularly where rough surfaces are treated, as to whether the rime exists or not, Dr. Milius therefore proposes an optical form of test other than that of the muriatic acid test, as is explained at length in his paper.

Dr Milius, in conjunction with Dr F. Foerster, has also

Dr. Millius, in conjunction with Dr. F. Foerster, nas also investigated the solubility, in water, of potash and soda glass, particularly with reference to Schott's experiments as to the capacity of potash water-glass for absorbing water without losing its vitreous quality. This latter fact can be ascertained by keeping pulveraced water-glass under water, when, as in the case of hydraulic cement, a hardening of the paste begins to take place. This pro-cess is connected with a development of heat; in the case of water-glass in which there was one atom of po'ash to three of silicic acid it was obseved at the Institution | valuable support from the State.

that within a quarter of an hour the moistened matter had been heated 10° Centigrade, and it became hard in one day; if the proportion of silicic acid is larger, the glass requires from two to three days for solidification. Their researches appear to show that for purposes con-nected with mercurial electrical standards, the glass used should be very little soluble in water and acids; hard glass, for instance, which had a base of soda, and not potash, being little hygrometric

In the important field of electrical measurements, the

Institution appears also to be doing good work. It is preparing to undertake the verification of all kinds of apparatus; including voltmeters, ammeters, meters for the measurement of power and efficiency, galvanometers,

and resistance coils.

In the field of practical photometry we have to com-pare the intensities of different sources of light as experienced by the eye, but unfortunately we have not, even for commercial purposes, any satisfactory method by which intercomparisons may be made between the relative intensities of coal-gas, electric and oil lights respectively. In practical photometry much is being done in this country by Abney, Vernon-Harcourt, Chaney, and others, as well as by Lummer, Brodhun, and others in Germany, but as yet no standard photometer has been produced. The standard light is still also the ancient "sperm-candle," and the method of comparison is still the old-fashioned "grease-spot" Bunsen photometer more or less modified. The German authorities appear to be fully alive to the necessity of improvement in this field of technical research; and have investigated M Violle's incandescent platinum-standard of light, and also the Hefner lamp and Aubert's apparatus; and for electrical light purposes they have followed a form of standard glow lamp.

Among the papers above referred to, we notice also one by Dr. Loewenherz, on the testing of tuning-forks. The Institution undertakes the testing of tuning-forks, on payment of a small fee, the object of the examination being to of a small ree, the object of the examination being to ascertain the correctness of the height of the tone of the fork in terms of an international diapason; or the number of the vibrations of the fork per second, at the temperature of 15° Centigrade, the pitch of the note A being fixed at 435 entire vibrations per second, or 870 half or single vibrations according to the French method of counting Tuning-forks sent to the Institution for examination are required to be constructed in accordance with conditions laid down by the Institution Unity of pitch is of fundamental importance in music and in the construction of musical instruments, and it is to be desired that some authoritative testing of tuning-forks might be similarly undertaken in this countr

In metallurgy the work of the chemical laboratories of the Institution does not appear to be extensive; it has included more particularly analyses of the metals platinum, cadmium, and rhodium. In the Physical Laboratory, measuring instruments of precision for workshop use, such as speed and power indicators, screw-thread gauges, have also been examined by the Institution; and its geodetical work has included the verification of instrurements of precision for General Schreiber, of the Imperial Prussian Land Survey. The department has undertaken also the verification of polariscopes, lenses, prisms, and other optical instruments, to a limited extent.

The above observations may serve to show that the Institution is alike prepared to verify a standard—as a measurer of electrical resistance—with the utmost accureconstruct of creatment resistance—with the utmost accuracy, or to test an instrument for common purposes—as a gas meter. How far the Institution may be self-supporting is not stated in the Director's Report; but as the demands for verification work of this kind are largely voluntary, it would appear to be evident that the excellent staff of the Institution could not be maintained unless it received

CRYSTALLIZATION.

THERE is something very factinating about crystalls. It is not merely the intrinsic beauty of their forms, sheir picturesque grouping, and the play of light upon their faces, which there is a feeling of wonder at the power of Naura, which causes substainces, in passing from the by plane faces, each substaince with its own set of forms, and its faces airranged with characteristic symmetry; some, like alien, in perfect ottabedra; others, his blue vitriol, in shapes which are regularly oblique. It is this content of the state of the st

We know that the external forms of crystals are instructed with their internal structure. This is betrayed by the cleavages with which in mice and selenite the properties of the properties and selenite departs are in season to the properties, and properties, and properties, and properties, and properties, and properties, and properties, angle and double refraction, and the effects of crystal on polaracel light. These familiar facts lead up to the thought that it is really the internal structure does not be the properties of the

Dallon fancied be had proved that the atoms of the chemical elements must be spherical, because there was no assignable cause why they should be longer in one assignable cause why they should be longer in one lasen no reason why the excursions of the parts of a molecule from the centre of mass should be equal in all mections, and therefore assume, as the most general case, that these excursions are unequal in different directions. And, since the movements must be symmetrical with the former of the centre of the cen

Here I may, perhaps, guard against a misconception. We chemists are familiar with the notion of complex molecules; and most of us figure to ourselves a molecule of common salt as consisting of an atom of sodium and one of chlorine held together by some sort of force, and it may be imagrined that these atoms are the parts.

the molecules which I have in mind. That, however, is not my notion. I am paradoxical enough to disbelieve altogether in the existence of either sodium or chloring in common salt. Were my audience a less philosophical one I could imagine I heard the retort from many a lip: "Why, you can get sodium and chlorine out of it, and you can make it out of sodium and chlorine !" But no. you cannot get either sodium or chlorine out of common salt without first adding something which seems to me of the essence of the matter. You can get neither sodium nor chlorine from it without adding energy; nor can you make it out of these elements without subtracting energy.

My point is that energy is of the essence of the molecule.

Each kind of molecule has its own motion; and in this I think most physicists will agree with me. Chemists will agree with me in thinking that all the molecules of the same element, or compound, are alike in mass, and in the space they occupy at a given temperature and pressure. The only remaining assumption I make is that the form of the ellipsoid—the relative lengths of its axes-is on the average the same for all the molecules of the same substance. This implies that the distances of the excursions of the parts of the molecule depend on its constitution, and are, on the average, the same in stances.

I have come to the end of my postulates. I hope they are such as you will readily concide. I want you to conceve of each molecule as having its parts in extremely rapid wibration, so that it occupies a larger space than it would occupy if its parts were at rest; and that the excursions of the parts about the centre of mass are on the average, at a given temperature and pressure, compared within a certain ellipsoid, that the dimensions of the control of

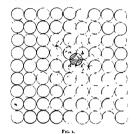

We have now to consider how these molecules will pack themselves on passing from the fluid state, in which they can and do move about amongst themselves, into the sold state, in which they have no sensible freedom. If they attract one another, according to any law, and for my purpose gravily will swifflice, then the laws of energy of the system shall be a minimum. This is the same, in the case we are considering, as saying that the molecules shall be packed in such a way that the distances between their centres of mass shall on the whole be the least possible, or, that as many of them as possible shall be packed into such a saying that the map the packed most in space. In order to see how this packing particular case in which the axes of the ellipsoids are all equal—that is, when the ellipsoids happen to be spheres. The problem is then reduced to finding how to pack the greatest number of equal spherical halls into a given space. It is easy to reduce this to the problem of finding how the spheres can be arranged so that each one shall show the spheres can be arranged so that each one shall the connered spaces between the balls, the unoccupied to the state of the state o

in the first place we may start with a square of halls, as in Fig. 1, where each is touched by four others. We may then place another (shaded in the figure) as as to touch the start of th

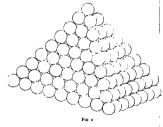

NO. 1129, VOL. 441

A Discourse delivered at the Royal Institution of Great Britain on Edday, May 15, 1891, by G. D. Lavetog, F. R. S.

Again, if we start with such a triangle, as in Fig 3, where each ball is touched by six others, we can place one ball —the shaded one—so as to rest on three others, and can then place six more round it and touching it, as in-dicated by the dotted circles In three of the triangular holes between the shaded ball and the dotted balls touching it we can place three more, so as to touch the shaded ball-again twelve touching it in all. If we complete

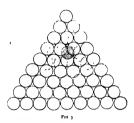

the pile, we shall get the triangular pyramid represented by Fig. 4, where each of the three sides is a right-angled triangle, while the base is an equilateral triangle. It will be seen that in the faces of this pyramid each ball (except those outside) is touched by four others. In fact, the arrangement in these faces is the same as in the base of the former pyramid; and the two arrangements are really identical in the interior, only one has to be

turned over in order to bring it into parallelism with the other. Fig. 2 represents half a regular octahedron, Fig 4 the corner of a cube Ellipsoids, if they are all equal and similar to one another, can be packed in precisely the same way, so that each is touched by twelve cisely the same way, so that each is touched by weive others, provided their axes are kept parallel to each other— that is, if they are all oriented alike. This, then, by the laws of energy, will be the arrangement which the mole-NO. 1129, VOL. 44]

cules will assume, in consequence of mutual attraction, in passing from a fluid to a solid state.

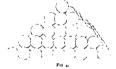

Next, let us see how the packing of the molecules will affect the external form. And here I bring in the surfacension. We are familiar with the effects of this force in the case of liquids, and if we adopt the usually received theory of it, we must have a surface-tension at the boundary of a solid, as well as at the surface of a liquid. I know of no actual measures of the surface-tension of solids, but Quincke has given us the surface-tensions of a number of substances at temperatures near their

points of solidification, in dynes per lineal centimetre, as-

Platinum Gold Zine Tin Mercury Lead , Silver Bismuth Potassium Sodium	· ·	 : :	983	Sulphur Phosphorus Wax	onate .	244 212 206 114 86·2 70 4 41·3 41 1 33 4

The surface-tensions of most of the solids are probably greater than these, for the surface-tension generally

diminishes with increase of temperature; and you see that they amount to very considerable forces. We have to do, then, with an agency which we cannot neglect. In all these cases the tension measured is at a surface bounded by air, and is such as tends to contract the surface. have, then, at the boundary between a crystallizing solid and the fluid, be it gas or liquid, out of which it is solidifying, a certain amount of potential energy, and by the laws of energy the condition of equilibrium is, that this notential energy shall be a minimum. The accepted potential energy shall be a minimum. theory of surface-tension is that it arises from the mutual

attraction of the molecules. The energy will therefore be a minimum for a surface in which the molecules are as closely set as possible.

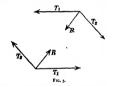

Now, if you draw a surface through a heap of balls packed so that each is touched by twelve others, you will find that the surfaces which have the greatest number of centres of balls per unit area are all plane surfaces. That in which the concentration is greatest is the surface of a regular ortachedron, next comes that of a cube, then that of a rhombic dodecahedron, and so naccording to the law of indices of crystallographers.

The relative numerical values of these concentrations are as follows, taking that of the faces of the cube as unity:—

Octahedron 1°1547 | Tetrakishexahedron 0°4472 Cabe 1°0000 | Eikositessarshedron 0°4083 Dodecshedron ... 0°7071 | Triakisoctahedron 0°3333

We do not know that the surface-tension is exactly in the inverse proportion to the concentration, all that we can at present say is that it increases as the concentration diminishes.

If then, the molecules occupy spherical spaces, the bounding surface will end to be a regular octahedron. But we have another point to consider. If a sold is bounded by plane surfaces, there must be edges where these planes meet. At such an edge the surface-tensions will have a resultant (see Fig. 2) tending to compress the mass, which must be met by a corresponding opposite mass, which must be met by a corresponding opposite must be a corresponding resultant of the tensions on the opposite side of the crystal. Hence, if one face of a form

is developed the opposite face will also be developed, and generally, if one face of a form be developed all the faces will be developed; and if one edge, or angle, be truncated. But the cross-gooding edges, or angles, will be truncated. Were it otherwise, there would not be a balance between the surface-transons in the several faces. But there is another point to be taken into account. The surface the tension per unit surface, or by reducing the total surface. When a liquid separates from another fluid, as another fluid, as the control of the form a solution of chloral hydrate on adding an alkalı, or a cloud from most air, the liquid assumes the form which, for a given mass, has the least surface—that is, the drops are spherical. If you cut of the procube or an octahedron, you bring it nearer to a sphere, and if you suppose the volume to remain constant, you soll diminish the surface. And if the diminishment of the total surface is not compensated by the increased energy on the truncations, there will be a tendency for the crystals to grow with such truncations. The like will be carried and the control of the provided the surface energy of the new faces is not to great as compared with that of the first simple form.

But it does not always happen that an octahedron of

NO. 1129, VOL. 44]

alum develops truncated angles. This leads to another point. To produce a surface in a continuous mass requires a supply of energy, and to generate a surface in the interior of any fluid is not easy. Air may be supersaturated with aqueous vapour, or a solution with a salt, and no cloud or crystals be formed, unless there is some discontinuity in the mass, specks of dust, or something of the kind. In like manner, if we have a surface already, as when a supersaturated solution meets the air or the sides of the vessel containing it, and if the energy of either of these surfaces is less than that of a crystal of the salt, some energy will have to be supplied in order to produce the new surface, but not so much as if there were no surface there to begin with. Hence, crystals usually form on the sides of the vessel or at the top of the When a solid separates from a solution there is generally some energy available from the change of state, hich supplies the energy for the new surface. But at which supplies the energy for the new surface. But at first when the mass deposited is very small the energy available will be correspondingly small, and since the mass varies as the cube of the diameter of the solid, whereas the surface varies as the square of the diameter the first separated mass is liable to be squeezed into liquid again by its own surface-tension. This explains the usual phenomena of supersaturated solutions. A deposit occurs partition of supersaturated solutions. A deposit occurs most easily on a surface of the same energy as that of the deposit, because the additional energy required is only for the increased extent of surface. It explains, too, the tendency of large crystals to grow more rapidly than small ones, because the ratio of the increase of surface. to that of volume diminishes as the crystal grows.

While speaking of the difficulty of creating a new sur-

face in the interior of a mass, the question of cleavage suggests itself. In dividing a crystal we create two new surfaces—one on each piece, and each with its own energy The division must therefore take place most readily when that surface energy is a minimum. the principal cleavage of a crystal made up of molethe principal cleavage of a ciystal made up of mole-cules having their motions comprised within spherical spaces will be octabedral. As a fact, we find that the spaces will be octabedral has a fact, we find that the fedral, or regular system, have octabedral cleavage. But not all; there are some, like rock salt and galena, which cleave into cubes, and a very few, like blendt, have their easiest cleavage dodecahedral. These I have to stances—as, for misance-funct-absences—which haves a series. stances-as, for instance, fluor-spar-which have a very distinct octahedral cleavage are rarely met with in the form of octahedra, but usually in cubes. In regard to this, we must remember that the surface energy depends upon the nature of both the substances in contact at the surface, as well as on their electrical condition, their tem-perature, and other circumstances. The closeness of the molecules in the surface of the solid determines the energy, so far as the solid alone is concerned; but that is not the only, though it may be the most important factor conducing to the result. It is therefore quite possible that, under the circumstances in which the natural sable that, under the circumstances in which the manufacture crystals of flour were formed, the surface energy of the cubical faces was less than that of the octabedral, although when we experiment on them in the art it is the other way. This supposition is confirmed by the well-known fact that the form assumed by many salts in crystallizing is affected by the character of the solution. crystallining is anected by the character of the solution. Thus alum, which from a solution in pure water always assumes the octahedral form, takes the cubic form when the solution has been neutralized with potash. To return to the cubic and dodecabedral cleavages. If we suppose the excursions of the parts of the molecule

To return to the cubic and dodecabedral cleavages. If we suppose the excursions of the parts of the molecule to be greater in one direction than in the others, the figure within which the molecule is comprised will be a prolate spheroid; if less, an oblate spheroid. Now, as already explained, the spheroids will be packed as closely as possible if the saxes are all parallel and each is touched

by twelve others. Now suppose the spheroids arranged sin Fig. 6, with their axes perpendicular to the plane of the figure, place the next layer in the black triangular spaces, and complete the pyramid. The three faces of complete the pyramid. The three faces of the properties of the place of th

Again, if the spheroids have their axes and greatest diameters in the ratio of $i \cdot \sqrt{\lambda}$, and we place four, as in Fig. 7, with their axes perpendicular to the plane of the figure, then place one upon them in the middle, and then four more upon it, in positions corresponding to those of the first four, we get a cubical arrangement, the centre of

a spheroid in each angle of a cube, and one in the centre of the cube. Crystals so formed will have cube symmetry, but the concentration of molecules will be greatest in the faces of the dodecahedron, and their easiest cleavage will be, like that of blende, dodecahedral.

If spheroids of any other dimensions be arranged, as in Figs. 1 and 2, with their areas perpendicular to the plane of Fig. 7, we shall get a crystal with the symmetry of the pyramidal system. If the spheroids be prolate, the fundamental octahedron will be elongated in the direction of the axis, and if sufficiently elongated, the greatest condensation will be in planes perpendicular to the axis, and the easiest cleavage, as in prussate of potash, in those planes. On the other hand, if the spheroids be sufficiently oblate, the easiest cleavage will spheroid be sufficiently oblate, the easiest cleavage will

be parallel to the axis.

If spheroids be arranged, as in Fig. 6, with their axes

perpendicular to the plane of the figure, they will, in general, produce rhombohedral symmetry, with the rhombs acute or obtuse, according to the length or shortness of the assess of the spheroids. The cubical form the control of t

occupy either the three adjacent white triangles or the three black ones. Either position is equally probable three black ones. The layer occupying the white triangles is in the position of a twin to that occupying the black triangles So far as the central parts of the layer are concerned, it will make no difference in which of these ways the molecules are packed. It is only at the edges that the surface-tension will be affected. If the form growing be a rhombohedron, a succession of alternating twins will produce a series of alternating ridges and furrows in the rhombohedral faces, which will give rise to increased surface-tension, which will tend to prevent the twinning On the other hand, an hexagonal form and its twin, formed in the way indicated, are identical, and we have in this fact a cause tending to the production of hexagonal forms This tendency is increased by the fact that, for a given volume, the total surface of the hexagonal forms is in general less than that of the rhombohedral Indeed, such forms lend themselves to the formation of almost globular crystals, as is well seen in pyromorphite and mimetite.

I 5Q

If the spheroids be arranged with their axes in other postions than those we have been discussing, or if the molecules occupy ellipsoidal spaces, they will, when packed so that each is touched by twelve others, give figures of less symmetry. The results may be worked out on the lines indicated in the foregoing discussion, and will be found to correspond throughout to the observed facts.

Bravais long ago proposed various arrangements of molecules to account for captaline forms, and Sohncke has extended them to further degrees of complication in order to account for additional facts in crystallography. But neither of them has given any reason why the molecules should assume such arrangement. To me to the control of the

We are now in a position to understand the interesting facts brought forward by Prof. Judd in a discourse delivered at the Royal Institution early this year However long a crystal has been out of the solution, or vapour, from which it was formed, it's surface-tension will remain unaltered, and when it is replaced it will grow exactly as if it had not been removed. Also, if any part be broken off it, the tension of the broken surface will, if it be not a cleavage face, be greater than on a face of the crystal, and in growing, the laws of energy necessarily cause it to grow in such a way as to reduce the potential energy that is, to replace the broken surface by the regular planes of less surface energy. The formation of "negative crystals" by fusing a portion in the interior of a crystalline mass, is due to the same principle. Surfaces of least energy will be most easily produced inside as well as outside, and in a crystalline mass of course they will be parallel to the external faces of the crystal. We see the same thing in the action of solvents. Most metals assume a crystalline texture on cooling from fusion, and when slowly acted on by dilute acids the surfaces of greater energy are most easily attacked, in accordance with the laws of energy, and the undissolved metal is left with same of clergy, and the unorsoived metal is left with surfaces of least energy which are the faces of crystals. This is easily seen on treating a piece of the plate, or of galvanized ron, with very dilute aqua regia. In fact, solution is closely connected with surface energy It is probably the low surface energy of one form of crystals of sulphur which makes them insoluble in carbon

disulphide, and this low surface energy may be an electrical effect.

I pointed out that the development of all the faces of a form, and the similar modification of all corresponding edges and angles of a crystal, is in general necessary in order to produce equilibrium under the surface-tensions. But we sometimes find crystals with only half the modifi-cations required for symmetry. In such cases the surfacedeform the molecules. When the crystal was growing, there must have been equilibrium, and therefore a pressure equal and opposite to this effect of the surfacesuppose that such a force would arise. The electric field might give rise to a stress in opposition to the aggregation of the molecules in the closest possible way, and then the crystal would grow such faces as would produce an equal and opposite stress Inequalities of temperature, or the presence of molecules of other kinds amongst those of the crystal, might produce similar results When the stress due to electricity, or to temperature, was removed by change of circumstances, that due to the surface-tensions would persist, and the crystal would be left with an internal strain. Crystals of this sort, with unsummetric Crystals of this sort, with unsymmetric betray the internal strain, either by internal strain Crystals of this sort, with unsymmetric faces, generally betray the internal strain, either by developing electricity of opposite kinds at the two ends when heated or cooled, or they affect polarized light, rotating the plane of polarization. That these effects are due to the internal strain is shown by the fact that tourmalines, and other crystals, which are pyro electric tournalines, and other crystals, which are pyro electric when unsymmetrical, show no such property when sym-metrically grown. Also sodium chlorate in solution, quarter when fused, and so on, lose their rotatory power Substances which in solution show rotatory power, as a rule develop unsymmetric crystals. This is well seen in the tartrates. The constitution of the molecules must be such that they will not, without some strain, form crystals; and equilibrium, when the crystal is growing, is attained by means of the opposing stress due to want of symmetry in the surface-tensions In all such crystals the rotatory power of the solution disappears in whole or in part We cannot test this in biaxial crystals, but, according to Des Cloiseaux, sulphate of strychnine is the only substance which shows rotation both in the solution and in the crystalline form, and in it the rotatory power is much increased by the crystallization. Effects comparable with these may be produced by mechanical means A cube of rock salt, which has no effect on plane-polarized light in its ordinary state, changes the plane of polarization when it is compressed in a vice. And a cleavage slice of prussiate of potash, which is uniaxial, may by compression be distorted so as to give in a convergent beam of polarized light elliptical rings, and two eyes like a biaxial crystal.

THE ERUPTION OF VESUVIUS OF JUNE 7,

DURING the latter part of 1800 and the early part of the present year, the central activity of Vesuvius has very slightly vaned, except about the new year, when it was considerably increased, rasing to the third or fourth degree, simultaneous with the stoppage of the lateral flow. Since then, up to the price of the lateral flow. Since then, up to the price of the lateral recommendation of the lateral flow. Since then, up to the price of the lateral activity has been generally at the first degree, and the cone of eruption has slowly grown in height.

On June 1 there was a crater within the central eruptive cone, of about 50 m in diameter, near the centre of which was the eruptive vent, surrounded by another embryonic eruptive cone. On that day, four small eruptive mouths opened around the embryonic cone in the bottom of the sentral crater, the smallest being to the east.

Thus the volcano remained till June 7, at 10 a.m., when

NO. 1129, VOL. 44]

activity stopped, only a small quantity of vapour escaping from central vents. At midday a radial cleft popend at the north toe of the cone of cruption (May 1889, June 1891) traversing towards its east end, the little sickle-shaped ndge, the remnant of the 183;-86 crater, but, as yet, age wo unlittle vapour. At 4 to 4 to p m, shocks of earth-quake commenced, limited only to the upper alopse to radial fissure down the side of the great Venuvian cone for nearly half its way opposite the Funta del Nasone of Monte Somma, from which, at about 5,30 pm, jusued a little lava, whilst from the upper extremity of the fissure at the toe of the once of crupton much vapour escaped, so that from Naples the smoke-plume arose from this point. From 35 to 7, pm the fissure still extended out the cone of crupton much vapour escaped, so that from Naples the smoke-plume arose from this point. From 35 to 7, pm the fissure still extended qualtes, notices, and the elevation of columns of black dusty smoke At a few munutes to 7 the floor of the Atrio del Cavallo was reached, and a remarkably black column of smoke had arssen.

My friend Dr. L Sambon saw this column arise, and came to inform me immediately, as I had left off watching came to moral me immediately, as I had left off watching the mountain at 5 30. After taking a photo of the mountain, we left Naples at 9 pm, spent some time in in quiries at Resina and near the Observatory Everything was now dark, as the volcano had caimed down at was now durk, as the volcano had caimed down at 8 p.m. At 2 am , June 8, we were at the eastern extremity of the Observatory ridge, and commenced to wend our way across the lava surface towards Monte Somma. We were at the lowest part of the depression at the west end of the Atton del Cavallo, where it joins the Fossa della Vetrana, and along which some of the largest lava-streams have flowed (1855, 1872, &c.), when suddenly on our right above us (2 23 a m.) a vast quantity of bright red vapour arose from the new outpour of lava. We hastened our steps as much as the road and our lantern would allow us, so as to reach the escarpment of Monte Somma, the foot of which was followed till near the Punta del Nasone, and close to the theatre of eruption. Here we clambered up some distance above the level of the Atrio to watch events whilst we ate our late supper or early breakfast. Along the slope of the great cone in the line of fissure were few lumnous points from some pieces of still uncooled lava of the little that had oozed forth from the lower half of the fissure At about 60 or 80 yards from the foot of the great cone two or three fountains of lava were throwing up jets of molten rock for 2 or 3 m, and the lava was slowly spreading out on the almost horizontal plain of the Atrio in several tongues The lava must have still been high in the main chimney, as the vapour that issued at the top of the fissure showed a slightly red illumina-So we remained till daylight, when we could see the fissure on the side of the cone. The mouth that formed at 5.30 the previous day was still smoking a little, whilst the fissure below it sent off several ramifications at an acute angle like the branches of an inverted tree, from several of which little streams of lava had been given out, where they had soon consolidated. We now followed the base of the great cone to the lower railway station, where we found all the people up and dressed, frightened by the strong shock and noises at 2.23 a.m., coincident with the fresh outflow of lava that we had witnessed, but which shocks we had not felt, although they were described as the strongest that had been felt

Having ascended to the summit of Vesuvius, we found the central crater rapidly enlarging by the falling in of its edges. From the new fissure at its summit was issuing much vapour under pressure, and rich in sulphurous acid, which is, even in traces, intolerable; and the hot air coming from innumerable new fissures rendered approach actions to the contract of the

side was equally unsuccessful At some old fumaroles on the 1872 crater plain, I collected some crusts of boric acid and alum, both rare products at this volcano. One of three terminations we may expect to these

One of three terminations we may expect to these phenomena, which are very characteristic of a lateral disruption, so common at Vesuvius.—

(1) Should the lava cool sufficiently to plug the radial

(1) Should the lava cool sufficiently to plug the radial dyke, no further phenomena will occur, and activity will be restored to the central vent.

(a) If this plugging only partially takes place, lava may dribble forth for months, but probably the escape of vapour will soon be restored to the central vent.

vapour will soon be restored to the central vent.

(3) If the rent should widen, considering how low it extends, we may expect a grand eruption which might gival that of 1872, which commenced near the same spot

and much in the same way; the mechanism by which this occurs I have explained elsewhere! My best thanks are due to Mr L Sambon for his company and help, and to Mr E Treuber, Inspecting Engineer of the Vesuvian Railway, for kind information Naples, June 9 H. J JOHNSTON-LAVIS

NOTES

A LAKOR and influential meeting was held at Edinburgh on Monday to consider the arrangements which ought to be made for the visit of the British Association to that eity nate year. The Lord Provos presided On the motion of Sir William Turner the following were elected Vice-Presidents —The Lord Provost, the Maquis of Lothina, the Earl of Konebery, Lord Kingsburgh, Principal Sir William Muri, and Prof Sir Douighas Macagian A local executive committee was chosen, and Mr A Gillies Smith was appointed honorary botal treasurer. In a text from Mr Griffith, secretizely of the Association, it was effect to the Mr Griffith, secretizely of the Association, in was facilitied to the secretized of the Mr Griffith Secretizely of the Association, in was facilitied to the secretized of the Mr Griffith Secretized to the Mr

On July 28 and the three following days, at Bournemouth, the British Medical Association will hold its fifty-ninh annual onetting under the presidency of Dr. J. Roberts Thomson. The schenific business of the meeting will be conducted in nine sections. An address in medicine will be given by Dr. Lauder Brunton; an address in surgery by Prof. Chiene; and an address in public medicine by Dr. Cox Seaton.

A PAYSICAL Observatory, furnahed with specially designed apparatis for the protection of investigation in radiant energy and other departments of tellune and autro-physics, has been established as a department of the Smithsonan Institution The communication of new memoris bearing in any way on such researches a requisted, and for them it is hoped that groper return can be made in due time.

THE Standard understands that on the vote for the salary of the President of the Board of Trade, either Sir Henry Roscoe or Sir Lyon Playfair will call attention to the action of the Government with regard to the proposed Institute of Preventive Medicine.

THE Committee of the French Academy has decided, by five votes to four, that the prize of 20,000 francs should be given to M Elhée Reclus, author of the well-known "Nouvelle Géographie Universelle" It is expected that the Academy will railfy the decision.

ACCORDING to a Reuter's telegram from Simla, dated June 22, Drs Rake and Buckmaster have succeeded in cultivating the leprosy bacillus in serum. They were alded in their researches by Surgeon-Major Thomson.

NO. 1129, VOL. 44

Its reply to Mr. Byce, a the House of Commons on Monday, the Lord Advocate stated that it would be the duty of the Government during the ensuing year not only to weigh very carefully the classing of secondary ductation in Socialand as one carefully the classing of secondary ductation in Socialand as one of the interests competing for a share of the additional Socioth or prosecute further inquiries as to the means by which any grant available for that purpose might be usefully applied. Many proposals had already been submitted to and considered by the Socioth Education Department, and these, as well as any suggestions which might be made, would receive well as applied for a supplied of the submitted of the submi

THE funeral of Sir Richard Burton took place on Monday at the church of Sir Mary Magdalene, Morilake The tomb represents an Arab tent, with a crucifix over the entrance. The interior is a small chapel with altar and some Oriental lights.

It has been decided that a Geographical Society shall be formed at Liverpool. A preliminary committee has been appointed, and it has issued a circular stating the objects of the new body.

ACCODING to a telegram sent through Reuter's Agency from Naples on June 16, the flow of the lava stream from Vessuvas had topped, and Sugnor Palmiers, the Director of the Observa tory on the mountain, had expressed his belief that the outflow might be regarded as at an end.

SLIGHT but continuous earthquake shocks were felt at Verona on June 10; and on the 11th, at 8 30 a.m. a very voluent shock occurred at Tregano and Badia Calavena. This was plainly felt in Verona also. Another violent shock occurred at Tregano on the 13th, and on the 15th shocks were reported from Castelnuovo, Peckhera, Somma Campagna, and Desenano

This first volume of a new meteorological Review has been published, containing observations taken in the south-west of Russia for the year 1890. This system was organized by Prof. A Klosowsky, in 1886, and now numbers nearly 600 observers. The observations refer chiefly to temperature, wind, rainfall, see, for chimatological and agracitural purposes. The Review also contains several strictle of importance, $\varepsilon_{\mathcal{K}}$ (1) on phenomena (1) on the harvest in connection with motivation of the contains of the contains of the contains of the contains the Russians language only, the positions of the stations, and various data referred to in the text, are illustrated by maps and diagrams.

Ar a meeting of the Royal Statistical Society, on Tuesday, a paper was read by Mr Noel A. Humphreys, Secretary of the Census Office, on the results of the recent census and estimates of population in the largest English towns. The first part of the paper was devoted to the consideration of the recently-usued results of the census in April last in the twenty-eight large English towns dealt with in the Registrar-General's weekly returns It was pointed out that, although the increase of population within the present boundaries of these Towns showed an increase of nearly a million in the last ten years, the increase was less, by considerably more than half a million (605,318), than would have been the case if the rate of increase had been the same as in the preceding ten years, 1871-81, and that the rate of movement of population showed striking variations in the different towns. The rate of increase in these twenty-eight towns, it was stated, has pretty constantly declined in recent years, and has fallen with scarcely a break during the last five intercensal periods from 24 3 per cent, in 1841 51 to 11'o per cent, in 1881-or. The percentage of increase within the bound-

aries of registration London (practically those of the county of London) declined in the same period from 21'2 to 10'4. The rate of actual decline of population in central London continues to increase, and the rate of increase of the other parts of the metropolis, including even the aggregate outer ring of suburban districts, continues to decline Examined In detail, the provincial towns show, with few exceptions, the operation of similar laws; actual decrease in the central portions, and marked deeline in the rate of increase in the other portions, the latter being specially nonceable in those towns with comparatively restricted areas. This examination, while showing the marked general decline in the rates of increase in these towns, discloses striking variations in the rates of increase in successive census periods Mr. Humphreys called attention to the fact that these striking changes in the rates of movement of population in the large towns interpose the greatest difficulty in estimating, even approximately, their population in intercensal periods. The estimate of population in Liverpool, based upon the rate of increase between 1871 and 1881, excoeded the recently enumerated number by more than 100,000, or by 20 per cent., while in Salford the percentage of over estimate, by the same method, was 26 per cent. recent birth-rates and death-rates in these two towns have been under-estimated by no less than a fifth and a fourth, respectively The various methods that have been at different times suggested for estimating the population of towns in intercensal years, in substitution of Dr. Farr's method, still used by the Registrar-General's Department, were severally considered, and it was shown that no hypothetical method yet devised affords reasonable promise of satisfactory results. It was therefore urged that

AT the meeting of the Linnean Society of New South Wales on April 20, Mr. T. W. Edgeworth David exhibited, on Abalif 20 of Mr. J. E. Carne, Mineratogut to the Department of Mines, Sydney, a speciation of precois opal from the White Cliffs about fifty miles northerly from Wilannius. Precious opal and common ogal have lately been discovered in this locality. In a formation corresponding to the Desert Sandatone of Questiand. The copied secons discensinated as an infillranced cement throughout the mass of the sandatone in place, and also replacing the calcutorous material of fosuit. It also occurs in cracks in the sandatone, and cacinonally replaces part of the original woody tussies of the silicified recommendations.

a quinquennial census could alone supply a remedy for the

present difficulty, which threatens to impair the public faith

in death-rates, the failure of which would most seriously hinder

and imperil the health progress of the country

MRS, J. KING VAN RENSSELAER contributes to the Proceedings of the U.S. National Museum an interesting paper on the playing cards used in Japan They are more distinctly original, she says, than any others, and show no marks of the common origin which the Italian, Spanish, German, French, Hindoo, and Chinese cards display. Forty-nine in number, they are divided into twelve suits of four cards in each suit. One card is a trifle smaller than the rest of the pack, and has a plain white face not embellissed with any distinctive emblem, and this one is used as a "joker." The other cards are covered with designs that represent the twelve flowers or other things appropriate to the weeks of the year Each eard is distinct and different from its fellows, even if bearing the same emblem, and they can be easily distinguished and classified, not only by the symbolic flowers they bear, but also by a character or letter that marks nearly every card, and which seems to denote the vegetable that represents the months. The only month that has no floral emblem is August, and that suit is marked by mountains and warmlooking skies.

NO. 1129, VOL. 44]

PROF. D'ACY W. TROMPSON has delted an interesting volume of "Sudies from the Museum of Zoology in University College, Dundee." The volume constst of the first twelve numbers of a journal in which the zoologies connected with the Dundee University College hope to find "an incentive to their own diligence, a way of communication with the outer world, and a means of gring direction and consecutive purpose to all and a means of gring direction and consecutive purpose to all and a mean first Mary I. Wulker, Prof. H. Lebosco, Dr. H. Si. John Brooks, Mr. Alexander Meek, and Prof. W. K. Parker

An interesting illustration of the antagonistic action of polsons is mentioned in the current number of the Pharmaceutical Journal. Dr Mueller, of Yackandandah, Victoria, has written a letter in which he states, says our contemporary, that in cases of snake bite he is using a solution of nitrate of strychnine in 240 parts of water mixed with a little glycerine Twenty minims of this solution are injected in the usual manner of a hypodermic injection, and the frequency of repetition depends upon the symptoms being more or less threatening, say from 10 to 20 minutes When all symptoms have disappeared, the first independent action of the strychnine is shown by slight museular pasms, and then the injections must be discontinued unless after a time the snake poison reasserts itself. The quantity of strychnine required in some cases has amounted to a grain or more within a few hours Both poisons are thoroughly antagonistic, and no hesitation need be felt in pushing the use of the drug to quantitles that would be fatal in the absence of snake poison. Out of about 100 cases treated by this method. some of them at the point of death, there has been but one failure, and that arose from the injections being discontinued after 14 grain of strychnine had been injected. Any part of the body will do for the injections, but Dr Mueller is in the habit of making them in the neighbourhood of the bitten part or directly upon it

The Rev. J. Hoskym-Abrahall writes to us that on June to, about 10 50 pm., new Woonkinch, he saw what he describes as "a benatiful phenomenon" "Suddenly," he say, "at the carelibe, and of the Great Bear, shone Grish a yellow globe, like Venus at her bnghten. Dropping somewhat alowly, it fell obliquely southward. As it passed in its brilliant eareer, it lighted up its dusky pash with a glorious lastre. When it had deseened about half-way down toward the horizon, to therefore a sparking host of glowing fragments, each dazsingly shot over with all the huse of the rainbow".

THE Register of the Johns Hopkins University for 1890-91 has been issued. It contains a great mass of well-arranged facts relating to the work of that flourishing institution.

MR C FRENCH, Government Entomologist at Melbourne, is contributing to the Victora Naturahit a series of notes on the insectiverous birds of Victoria. In the first paper, which appears in the May number, he describe the Australian Bustard (Charsatia sustraint). Some months ago Mr. French made an appeal to the Victorian Government for the personant protection of this, the most useful insect-destroying bird in the colony. It appeal was supported by the Council of the Zoological Society of Melbourne; and the Government has not only acceded to the request, but has placed the matter before the Government of New South Wales, who, it is hoped, will at once see the necessity for the preservation of a valuable a bird.

DR. A. KORNIC has issued as a separate volume the account of his ornithological observations made during his explorations in Madeira and the Canary Islands. It is a notable memoir, and several new species and sub-species of birds are described. He is somewhat severe on some British ornithologists for having

tried to forestall lam in the description of the Chaffinsh of Plams, which he was the first to discover. The edutor of the fournal fur Ornsthologes, in which the paper first appeared, also adds some strictures on the ways of British naturalists. Dr. Koemig apparently has some grounds for his complaint, but a resease a Regular by his new name of another, though he admits earling a Regular by his new name of another, though he admits that the British Museum "Catalogue of Pirch," in which he will find that his identifications of the Maderan and Canarian Frengilla were all published long before height them to world as new facts. These small outtere do not, however, affect the importance of the essay, which is work do unt he rearstable acre, and is, in fact, a monographic review of the ornsthology of Madera, Teastiffs, and Palms. Eight coloured places tilustrate the

In a paper lately read before the Sclennife Section of the Manchester Literary and Philosophical Society, Mr John Watson maintains that the re-development of lost limbs is not unusual among insects. He hunself has had three cases in which limbs have been re-developed, and one case of complete cicatrization. Re-development, he says, can take place either at the larval of the pupil stages of an insect's neutrophosis

THE British Consul at Hankow, writing of the varnish exported from that city, says he is informed that it is the gum of a treethe Rhut vernicifera. On this tree, before daylight, incisions are made: the gum that runs out is collected in the dark, and strained through a cotton cloth bag, leaving behind a large amount of dirt and refuse. This operation can only be performed in the dark, as light spoils the gum and causes it to cake with all the dirt in it. It cannot be strained in wet weather, as moisture causes it to solidify. When the Chinese use this varnish, they rub it on with a sort of mop, or swab, made of soft waste silk. It should only be used in wet weather, as, if the atmosphere is dry when it is rubbed on, it will always be sticky As used by the Chinese, the varnish takes about a month to dry, and during the time it is drying it is poisonous to the eyes. The Consul thinks that this gum may have been one of the ingredients of the celebrated Cremona varnish, and he suggests that it might be worth the while of musical instrument makers to make expenments with it with a view to producing a varnish that would give a mellow instead of a glassy sound.

THE Insect-house in the Zoological Society's Gardens is now in excellent order, and well deserves a visit. In addition to the Silk-moths that are usually present during the warm weather, the Papilioning, or Swallow tail butterflies, afford at the present time the chief display The perfect insects of several species of the genus Papilio have appeared-P. cresphonies, asax, and asterias from North America, P alexanor from the Mediter ranean shores, and the handsome P. maackss from Japan. The last-named has been seen for the first time in the house this year, and offers a striking contrast to the other species of the genus that have previously been exhibited in the Gardens, it being of black and golden-green colours instead of the yellows and blacks that we are accustomed to in our European Swallowtails. P. cresphontes has appeared in large numbers in the house, but no varieties have been obtained. This also is the first season for two other besutiful Papillonine, viz. Dorstis apollina from Asia Minor, and the Japanese Sericina telamon The latter shows considerable difference in the markings of the sexes. The North American Limenitis disspous can be at present seen in all its stages, and is well worthy of attention, the caterpillar moving along the leaf-stalks with a peculiar interrupted gait. Of the Sphinx moths, the South European Deilephila alecto has already appeared, and D. wice is expected. These insects are, however, not seen to advantage in confine-

ment, as their superb powers of flight cannot be displayed in a small compartment. Two examples of the Orthoptera are alive in the house-Draphemora femorata, one of the Suck- or Twiginsects from North America, and Empusa egena from Southern Europe. The former has been reared from eggs laid in the Insect-house, but these progeny are not so healthy as those obtained from freshly-imported eggs. The Empusa is of a most bigarre form, and belongs to the family Mantides, the species of which feed only on living creatures. The public is Indebted to Mr. S. H. Carver for the opportunity of seeing living scorpions; he has sent examples of two species of this group from Egypt, both of which unfortunately are unidentified, there being obvious difficulties in the way of carrying about live scorpions and comparing them with dried specimens. There is a third scorpion, from South Europe, living with its Egyptian congeners : it has a small delicate tail, and is altogether a less frightful creature. though assuming a menacing attitude with equal readiness. spider, Lycosa portosantana, from Madeira, is healthy, and is a fine creature, though insignificant by the side of its neighbour. a huge Mygale from South America. The latter, as well as the scorpions, is fed with mice, which are given to it dead, though in its native haunts a Mygale has been known to prev on living individuals of these small mammals,

In the current number of the Board of Trade Journal some interesting facts as to cotton cultivation in Russian Turkestan are given, on the authority of a Russian correspondent of the Monde Economique. After the submission of the Khanates of Central Asia, the trade of the country was carried on chiefly with the towns of Russia in Europe, and was confined at first to the export in small quantities of cotton grown from native seeds, of rice, raw silk, and other similar products. It is only during the last ten years that the industry of the country has extended to any considerable degree, owing to the ingress of speculators, and has changed its primitive character. There have been established all kinds of works and factories, and in 1884 the cultivation of cotton of American origin was essayed. This trial succeeded so well that all classes of society, including even public officials, devoted themselves to this culture, which has become one of the chief branches of industry in the country. The new cotton produced in Central Asia is equal to that of America, and finds an excellent outlet among the cotton spinneries and mills of Russia. But the consumption in European Russia does not suffice for the ambitious aims of native producers, and they look forward to the possibility of opening up trade in the foreign markets of Europe.

THE new number of the Internationalist Archiv fur Ethneorgatis fally mantains the reputation of this excellent periodical. Among the contents is a paper in which Dr. J. D. E. Schneilt, continues his elaborate account of the collections from Corea in the ethnographical museum at Leyden. Dr. Hennrich Schurz: has an interesting article on the geographical distribution of negro continues. As usual, the plates illustrating the vanous contributions are most carefully secured.

A FURTHER communication upon the new personde of sulphur, SO₀, by Prof. Trush, of Bireslaw, will be found in the current number of the Bernelle. Thus interesting substance is obtained when solutions of sulphure and containing at least 40 per cent. of and are subjected to electrolysis, as a crystaline deposit upon the anode. The crystals were finit observed some time ago by Berthelot, but were considered by him as identical with the oxide SO₀, which had periodically obtained by the science of the size of the crystal sever finite or supplied to the control of the size electrical dicharge upon a mixture of supplier dicade and tunnel at the anode in the electrolysis of 40 per cent, columns of sulphuric acidd in represented by the formula SO₀, and in quite a different substance from Berthelot's SO₀. It is, as predected by

Mendeleeff, not the anhydride of an acid, but a neutral oxide of a similar chemical character to hydrogen peroxide. It may be best separated from the excess of 40 per cent, acid by removing the latter, after dilation with three times its volume of water, by means of freshly prepared barium phosphate. It cannot, however, be preserved in pure water, as it parts with oxygen so readily, becoming reduced thereby to ordinary sulphuric acid. That it is not an anhydride is proved by the fact that it yields no salts of the type K2SOs with alkaltes. Neutral solutions containing it, in which it appears to be permanent, may be readily prepared by neutralizing the solution in 40 per cent acid with caustic soda, potash, or magnesia. The properties of SO4 in either acid or neutral solution are somewhat remarkable. Whea boiled in contact with platinum wire or platinum black it is energetically decomposed with evolution of quantities of oxygen. If the neutral solution is employed, it becomes strongly acid Indigo solution is oxidized and decolorized slowly, but instantly if a little ferrous salphate is added SO, however, in spite of this ready decomposition into oxygen and sulphuric anhydride, is but a weak oxidizing agent, being incapable even of oxidizing oxalic acid or carbon monoxide But under certain circumstances it acts as a powerful reducing agent For instance, if an emulsion of peroxide of lead in 40 per cent. sulphuric acid is brought in contact with a quantity of similar acid which has been subjected to electrolysis so as to charge it with SO4, a rapid evolution of oxygen gas occurs, and the peroxide of lead is converted into ordinary sulphate of lead. In a similar manner precipitated peroxide of manganese is rapidly reduced to manganous sulphate with evolution of oxygen, and silver peroxide likewise dissolves up to a clear solution of stiver sulphate with violent effervescence due to the escape of oxygen Prof. Traube regards sulphur peroxide as built up on the type SO₂(O₂), resembling hydrogen peroxide, HaO, He considers that Berthelot's oxide, SaO, is a molecular compound of SO, and SO,, for it does not dissolve in water without decomposition, breaking up into sulphuric anhydride and oxygen, which is evolved On the other hand, it appears, like SO,, to be perfectly stable in a moderately concentrated solution of sulphuric acid.

164

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (Macacus cynomolgus &) from India, presented by Mr. James B. Leekie, a White-fronted Amazon (Chrysotis leucocephala) from Cuba, presente | by Mrs. Lacabra; a Radiated Tortolse (Testudo radiata) from Madagascar, an Angulated Tortoise (Chernina angulata), three Smooth-bellied Snakes (Homolosoma Intra.) from South Africa, presented by the Rev G. H. R Fisk, C.MZS, a Green Lizard (Lacerta viridis) from France, presented by Mrs Hill; three Horned Lazards (Phrynosoma cornutum) from Texas, presented by Mr James E Talmage, five Squirrel-like Phalangers (Belideus neureus & & & & Q) from Anstralia, a Grand Eclectus (Eclectus roratus) from Moluccas, deposited, two Elliot's Phensants (Phassanus ellists 9 9) from China, two Rufous Tinamous (Rhynchotis rufescens) from Brazil, purchased; two Marbled Newts (Molge marmorata), bred in the Gardens,

OUR ASTRONOMICAL COLUMN

NEWL-DISCOURSE MERSINGS ON SATURA.—Edinburgh Circular No. fig. useed by Dr. Copeland on June 10, contains Mr. A. Stagley Williams, of Burgess Hall, Susse, hat discovered three deletate but distinct markings in the equatorial argono of Satura. The first and their of these are round bright segroon of Satura. The first and their of these are round bright which they occur. The second is a smaller dark marking on the equatorial edge of the shaded belie which forms the southern boundary of the white zone. Mr. Williams has obtained shear the content of the conte at requires patience and practice to see them readily. It is very

desirable to obtain repeated observations of their times of transit across the planet's central mendian. To facilitate these observations, Mr. Williams has prepared the following table, using 10h, 14 6m. as the provisional time in which the planet rotates On the exist.

THE ROTATION PERIOD OF VENUS -The Bulletin de l'Aca-THE ROTATION PERIOD OF VENUS—The Buildish de l'Aud-deun Royale de Belgaun, No. 4, coatanns a paper, by M. Niesten, of Brussels Observatory, à proper the rotation of the planet Venus. The observations and drawings made by M. Suyvaert and the author from 1831 to 1890 do not appear to confirm the persist-ence of the dark markings during a long period, as found by Schinparelli and other. It is also shown that De Vico'l period. of 23h. 21m 21'93s, is more in accordance with the observa-tions than Schiaparelli's period of 224 7 days Twelve drawings of the planet, and a map showing all the markings, accompany

A NEW ASTEROID (10) -M. Charlois discovered the 310th minor planet on May 16. Its magnitude was 13.

THE ROYAL GEOGRAPHICAL SOCIETY.

THE ROYAL GEOGRAPHICAL SOCIETY.

THE answersy meeting of the Royal Geographical Society
The answersy meeting of the Royal Geographical Society
The first basis of the Royal Control of Monday after
noon, the Forestee was the award of the medial and obten
honour for the year. The Founder's Medial was delivered to
So Dillon Bell, Agent-General for New Zealand, for transmisSor Dillon Bell, Agent-General for New Zealand for transmisreceived the Parton's Medial on behalf of Dr. Fridgity Nasson,
New Zealand Geological Survey. The Swedish Minister
received the Parton's Medial on behalf of Dr. Fridgity Nasson, ho was unable to attend. Other hogours were awarded to Mr. who was nable to attend. Other hosours were awarded to Mr. Wilsam Gylter, for his explorations of the Mackemase and Yukon with the exploration of Nyssaland, Mr. A. E. Pratt, for his pourneys in Sechuen; Mr. W. J. Stealas, for his investigations on the Rio Doce, South America. Mr. H. J. Mackinder then introduced the students of the Training Colleges who had been successful ia obtaining the prizes offered by the Society annually on the results of the Christmas examinations in geography. Mr. Mackinder spoke briefly on the progress of geo-graphical education, and on the results of the four years' awards to the Training Colleges

The Secretary then read the annual report of the Society, from which it appears that on May I last the total number of Fellows which is appears that on May I last the total number of Fellows was 3579, being a net increase of \$6, on the previous year. The total income up to the end of December 1890 was 19531, and expenditure 1820. The estimated value of the Society's investments is 12,568, and of its total sasets 16,628. During the past year, 900 books and pamphlets have been added to the illurary, and 936 sheets of map to the map collection, besides 25 atlases, 700 photographs, 151 lantern-slides, and 51 views.

The President then proceeded to deliver the annual address on the progress of geography during the past year, dealing mainly with the explorations which have been carried on in

various parts of the world.
"The year," he said, "of which I am about, with your permis-"The year," he said, "of which I am about, with your permis-sion, to give some account, has not been, so far as geographical discoveries are concerned, a very brilliant or sensational one Brilliant and sensational years are, also hikely to grow fewer and fewer as the globe we inhabit becomes ever better known and fewer as the globe we inhabit becomes ever better known to it. If, however, the year has not been made mem rable by much extensive exploration it has put to its credit no small amount of instensive exploration. A good many gaps in our knowledge have been filled up, and a great deal of solid useful work accomplished. All this healthy activity has been represented in our Proceedings, and much of it has found its way to santed in our Proceedings, and much of it has found its way to un'fellows through the papers which have been read in this theater. Many of these have been extremely interesting. If Cogleg's journey to Uganda, Colonel Tanner's observations on the Hunslayan Range, and Mr. Pratt's journey to Succhuen These last were distanted, at it will be remembered, by drawings and by photographs of exceptional ment, which were examined correlately by large namelyes after our examined correlately by large nameless after our neetings closed examined caretury by targe manuals and the auditors, the total assets of the Society have considerably increased, and we total assets of the Society have consuderably increased, and we are in a position to give most efficient assurance to any tho-roughly well considered whether which are laid before us. I although we are rich, if is not not the less our day to cartuinte carefully all proposals which are made to us, and to see that the money which they give so generously is applied only to really promising objects. Such we considered to be Mr. Kaussay's explorations in Asia Minor, and Mr Theodore to really promating objects. Such we considered to be the control of the control are being crowned with success, thanks to the enigenency towers now prevailing there, to the powerful assistance of the Warden of Merion and other friends in high place, and to the zeal and high intelligence of Mr Mackinder, who is rapidly winning not only golden opinions for himself, but an excellent place for his senence on the banks of the Iss. Negotiations are Negotiations are place for his scenece on the banks of the fass 'Negotasuous are mown in progress which will, I hope, result in the establishment of a Traveling Scholarship at the joint expense of our Succept of a Traveling Scholarship at the joint expense of our Succept when the progress of the Succept Scholarship at the joint expense of our Succept Scholarship at the progress of the Succept Scholarship at the S able ways

The President then proceeded to review the exploring work of the year, most of which has already been dealt with in NATURE.

PARKA DECIPIENS

THIS very interesting fossil is derived from various localities in Scotland, all of which are believed to be Lower Devonian. It was first described in 1831 by Dr. Fleming, and the the beau recorded on the state of since then has been noticed on several occasions, and variously

1 "Notes on Specimens from the Collections of Messre Graham and Reid, by Sir Wm. Dawson, LLD, F.R.S., and D. P. Penhallon, B.Sc. F.R.S.C. Abstract of a paper read before the Royal Society of Canada May 1891

NO. 1129, VOL. 44

regarded as the spawn of Mollusca or Crustaceans, and as of

regarded as the spawn of Mollusca or Crustaceans, and as of wegetable origin.

The material upon which the present observations are based was collected by Mr. James Read and Mr. Walter Graham, both of whom have offered many valuable suggestions as to the probable nature and affinites of the fossil. As found, the Tair ha deraption usually consists of oval masses bearing rounded impressions or data-like bodies of carbonaceous matter. Assomether than the contract of the contra impressions or disk-like bodies of caroonaccous matter. Asso-cated with these are also stems and linear leave of two dimen-sions, and a third form having a general resemblance to Pachy-theca, which is found in the same beds, and differing from it in having a more discold form, and being devoid of structural

The authors show that the fossil is probably a rhizocarp allied to Pulularia, and that there are at least three forms recognizable, of which one is referred to the species, and the other two to varieties. The views thus stated are based upon differences of size and upon the fact that certain of the disk bodies show spores of two kinds, and in some cases prothall in various stages of development, all derived from the same sporocarp

The paper is illustrated by a plate of figures

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE -In the list of the Mathematical Tripos (Part It) Mr. Bennett, of St John's, the Senior Wrangler, Mr. Crawford, of King's, the fifth Wrangler, and Miss Philippa G. Fawcett. "above the Senior Wrangler." are placed in the first division of the First Class.

SCIENTIFIC SERIALS

The American Milestrational formula for May contains the following articles —Cold waves, by Prof T Russell. In the report of the Chief Signal Officer for 1889, he expressed the view that the origin of cold waves was due to mixture of upper and lower air causing cooling of the layer next to the ground. On further examination of the subject, in connection with the observations at mountain station, he admits the incorrectness of those views, and states that, while it is essential to connect the low temperature and high pressure in some way, the cooling of the ground by radiation, and of the air by contact and conduction, will not completely explain the cause of cold waves -How tion, will not completely explain the cause of cold waves—How could the Weather Service best promote agriculture?, by M. W. Harrington The American Weather Service has hitherto devoted itself more particularly to the interests of commerce, while the State Services have had the interests of farmers more distinetly in view What the farmer wants to know is, where and tinctly in view What the farmer wants to know is, where and when a local shower will fall. While the complete solution of this problem may be impossible, the approximate solution has in the multiplacation of local forecasting stations, and in the intelligent use of the indications of the Central Office, combined with the indications which he can himself observer. The author recommends more attention to climatology as distinct, from recommends more attention to climatology as distinct from weather changes, and to the relations between plants, soil, and meteorology,—Is the influenza spread by the wind?, by H. H. Hildebrandson. This is a translation, by the author, from an article in the Journal of the Medical Society at Upsala, and is, practically, a reply to an article in NATUREOF December 19, 1889, where it is stated that the mailedy is probably spread by the wind. The author shows, by a map and table, the places and dates at which influenza occurred in Sweden, from inquiries of medical men The result of the research goes to show that the influenza is propagated by infection, that it is conducted from place to place through human circulation, and that the time of incubation is two to three days. The state of the weather seemed to have no influence on the spread of the malady; in fact, it raged with the same severity in countries possessing very different climates, and during very different weather conditions.

SOCIETIES AND ACADEMIES. LONDON.

Royal Society, June 4 - "On a Determination of the Mean Density of the Earth and the Gravitation Constant by means of

⁴ Mr Reid acknowledges his indebtedness to Mr Langlands, the lessee of Myreton quarries, whose kind permission to examine these quarries was as freeby granted.

the Common Balance." By J. H. Poynting, D. Sc., F.R. S., Professor of Physics, Mason College, Birmingham.

In a paper punted in the Proceedings of the Royal Society, No. 190, 1979, an account was given of some experiments. No. 190, 1979, an account was given of some experiments and the second of are known. Having found G, we may determine the mean density of the earth, for, assuming that it is a sphere of radius R, the weight of any mass M' at its surface is

$$G \times \frac{1}{2}\pi R^2 \Delta M'/R^2$$

= $\frac{1}{2}G\pi R \Delta M'$.

But if g is the acceleration of gravity the weight of M' may be expressed as M'g. Equating these values, we get

$$\Delta = \frac{1}{6\pi R}$$

Method of Using the Common Palance,—With the length of beam used (about 12 cm) a differential method was applicable, beam used (about 12 cm) a differential method was applicable, as perment masses of lead and actionmony, about 21 kloss, such, were buing from the two arms of the balance, so that their centres of the state of the was calculated and allowed for

The alteration in the weights of the attracted masses, due to the motion of the attracting masses from one side to the other, was the quantity to be measured. When this was determined in the lower position of the attracted masses they were raised to in the lower position of the attracted masses they were raised to about double the distance, and the attraction again determined. The difference eliminated the pull on the beam, suspending wires. &c. To lessen the effect of want of homogeneity or sphericity in the masses, or of want of symmetry in the turn-table, the masses were all inverted and changed over each to the

table, the masses were all invertee and canaged over sean to use other side, and the weighings repeated.

The position of the beam was determined by the reflection of a scale in a mirror used with "double suspension." The mirror was suspended by two silk threads, one attached to the end of the ordinary pointer about 60 cm. below the central knife edge, the other parallel to it, being attached to a fixed support.

The mirror turned through an angle about 150 times as great as that through which the beam turned, and one scale division corresponded to an angle of tilt in the beam of about 2/15ths of 0.50

a second. The value of a scale deviation was determined by the use of The value of a scale deviation was determined by the use of wind the office of the configuration of the large beam. When one rider was placed on one supporting frame the other was at the same mainst filled off the other frame. The balance was left free throughout a sense of weighings and no morning parts of the appraisate were connected with

the case.

The values obtained are as follows :---

The gravitation constant $G = \frac{6.6984}{1}$ Mean density of the earth & = 5'4934.

In the paper a description is given of a new form of NO. 1129, VOL. 44]

"Quadrant Electrometers," By W. E. Ayrton, F.R.S., J. Perry, F.R.S., and W. E. Sampner, D.Sc.
In 1886 it was noticed, on continuously charging up the needle of Sir William Thomson's bifair suspension quadrant electrometer No. 5, made by Mesar, White, of Clargow, and in use at the laboratories at the Central Institution, that the in See at the laboratones at the Central Institution, that the deflection of the needle, where the same F.D. (potential diffractions) and the needle, where the same F.D. (potential diffractions) are same for the same form of the same form of the same for a large charge on the needle as well as for a sami, the semblity of the instrument was small. A similar effect had seen that the same for the same form of the attraction of the needle, which wares with the square of the needle's charge, increases the pull on the biflar suspen-sion, and so for high charges more than compensates for the increased deflecting couple due to electrical action. On rassing, however, the needle of our electrometer much above the centre however, the needle of our electrometer much above the entire of the quadrants, the anomalous variation of sensibility of the instrument with increase of charge in the needle did not districted the control of the con

The needle was carefully weighed, with the platinum wire attached and the weight dipping into the acid, and a calculation was made as to the magnitude of the effect that should arise was made as to the magnitude of the effect that should arise from the change of the pull of the Bree due to any upward or downward attraction of the needle by the quadrant. That continue the properties of the pull of the pull of the state needle and the quadrants, the amount of such attraction was quite unable to account for the observed diministion of sensi-toring the pull of the pull of the pull of the pull of the state of the pull of the pull of the pull of the facts at the pull of the pul rate in our specimen of the quadrant electrometer, the principal

rate in our specimen of the quadrant electrometer, the prancipal part of the anomalous action was not caused by an increased issues not of the fibres, and that therefore some other cause must be looked for to explain the observed results. We therefore decided to make a complete investigation of the laws connecting the variation of the sensibility of the instrument with the potential of the needle, the distance between the fibres, the distance between the quadrants, and the position of the needle.

The results of the investigation, briefly summed up, are as follows :-

(1) The quadrant electrometer, as made by Messrs White, (1) The quadrant electrometer, as made by Messrs White, although it may be acceptable adjusted for symmetry, does not neatly even approximately obey lie recognized law for a quadrant electrometer when the potential of the needle is altered. (2) The peculiarities in the behaviour of the White electrometer when the properties of the White electrometer when the white white white the properties of the White electrometer when the properties when the

meter are due mainly to the electrical action between the guard tube and the needle, and to the slight tilting of the needle that occurs at high potentials.

(3) By special adjustments of the quadrants of the White electrometer, the sensibility can be made to be either nearly independent of the potential of the needle, or to be directly proportional to the potential, or to increase more rapidly than the potential of the needle.

(4) By altering the construction of the instrument, as described, the conventional law for the quadrant electrometer is obtained without any special adjustment of the quadrants beyond that for symmetry, and the instrument is rendered many times as sensitive as the specimen we possess of the White pattern.

Linnean Society, June 4.—Prof. Stewart, President, in the chair—After nominating as Vice-Presidents Mr. A. W. Bennett, Dr. Brathwatte, Mr. F. Crisp, and Dr. St. G. Mivart, the President took occasion to refer to the loss which the Society had President took occasion to reter to the loss which its Society had sustained by the recent death of a Vice-President, Prof. P. Martin Duncan, F.R.S. His genial presence at the meetings, no less than his valued contributions to the publications of the Society, would, he felt aure, be missed by everyone.—Sir Walter Sendall, who was present as a visitor, exhibited a curious cocoon of a unth helonging to the genus Times, and made some remarks on its construction and specialtic coloration—The President exhibited a case of Leptodeptra and Colorates, which he had selected to illustrate some of the more notable secondary sexual characters in insects, and made some unteresting explanatory of Months of the Colorate of the Colorate of Months of the Colorate of the Colorate of Months of the Colorate of the Col

EDINBURGH.

Royal Society, May 18 -The Hon, Lord Maclaren, Vice-President, in the chair. -Dr. Buchan read a paper on the barometer at Ben Nevis Observatory, in relation to the direction and strength of the wind. In arranging the results, Dr Buchan has referred the direction of the wind to sixteen points of the compass, although the observations are actually made with reference to the thirty-two points. The readings of the barometers at the high level and the low level stations, when reduced to sea level, exhibit marked differences dependent upon the direction of the wind. The Investigation extends over the the direction of the wind. In a investigation extends over the period of nine months commencing in August 1sst. During that time, all the very high winds have been from the east-outh east and the south-east, these being the directions in which the wind blows freely along the top of the mountain to the Observatory. In eleven cases the wind from these directions attained a speed of 120 milet an, hour or more, and the (reduced) barometer at the high level station read about one eath of an inch lower than the instrument at the low level station In no other direction was a higher velocity than 70 miles an hour noted, and in the directions from west to north-northbour noted, and in the directions from west to north-north-west, cast, and est-north-east, we belong was never greater than 30 miles an hour. With northerly winds the instruments at the top of the mountain record as much lower speed than that which, from observations of the drift of the clouds, is seen to be reached at a small height above the top of the mountain. The case of this comparative calm immediately at the top as the mapper of the air upon the face of the chird which lies to the north of the Observatory. The stream have are then weldered to the control of the control of the chird which could be a support of the chird. defected appareds. In such cases the depression of the bar-ometer is about three times ag reat as that which cours with an equally strong wind from other directions, and indicates the for-man of the strong time. The strong course is a strong popular popular result which is observed with other directions of the wind is that the (reduced) high level barometric reading exceeds he (reduced) to revel reading when the want blows as about the speed of the wind exceeds that rate, on the one hand, or is extremely small, on the other. This seems to indicate an in-tercent time of the strong course of the speed of the speed of the speed of the wind exceeds that rate, on the one hand, or is extremely small, on the other. This seems to indicate an in-tercent time of the strong time of the speed of the and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is and to may explain the fact that the top of the mountain is meant of the leaver, while dense cloud is being constantly formed at a about distance above it.—Dr. J Berry Hayeraft gave an entirely of the strong time of the strong time of the strong time of the mean of the leaver time of the strong time of the strong time. ments of the heart, which since Harvey's time are supposed to ments to the neart, which since travey a time are supposed to take place with every contraction, do not really occur in the unopened chest, and (3) that the cardiogram has been missister-preted by physiologists I it is usually supposed that, during each contraction, the heart twists towards the right while its spex moves forward, and, pressing against the wall of the chest,

causes the "apex beat." Again, it has been supposed by some that, during expansion, all diameters of the heart are not increased, but that, on the contrary, one diameter is diminished in creased, but that, on the contrary, one diameter is diminished in length. Dr Haycrafi's experiments show that all diameters are increased during expansion, and that all are diminished during contraction. They show also that the motions, above described, do not occur in the unopened chest. The heart, in described, do not occur in the unopened enest. The heart, in order that it may be observed in the opened ehest, is necessarily separated from its attachments and falls towards the back of the separated from its autactments and tails towards the said of the chest (the animal operated upon being supposed to be placed upon its back) During expansion, the heart becomes flaced, and so is flattened against the back of the chest and so is flatiented against the back of the chest. The first effects of the suffraing which occurs during the muscular contraction is therefore an elevation of the heart, against gravity, cowards the frost of the chest. Similarly, if the animal be found to the chest of the chest of the chest of the chest, and the "beat" can even be made to take place towards the back. In the unopened whest, the heart on the whole remains in position drang contraction, and therefore it is boundaries move from the chest walls. The first But the cardiogram, as usually interpreted, shows that the chest wall is thrown outwards by the impact of the heart during conwall is thrown outwards by the impact of the heart during con-traction. Dr Haycraft asserts that this is due to deformation of the heart by pressure of the chest wall when the button of the cardiograph is pressed against the exterior of the chest. The hist effect of the mucular contraction and stiffening of the heart is therefore increased pressure against the chest-wall, which gives rise to the up-stroke of the cardiogram. When the cardiograph is made as light as possible, the up-stroke is greatly diminished, but it never entirely vanishes, because the fitch heart is always slightly distorted by the chest wall even when the cardiograph is not pressed against it Dr Haycraft further hows that the sinuosities, which always appear to a greater or less extent on the cardiogram, are not due to peculiarities in the action of the heart, but are instrumental in their origin, being caused by oscillations which result from the inertia of the caused by oscillations which result from the mertis of the cardiograph—Dr. High Robort Mil read a paper on the chemical composition of its vaters. He described records, and discussed observations, made by himself and other members of the staff of the Scottah Marine Statoo. The observations deal the staff of the Scottah Marine Statoo. The observations deal the staff of the Scottah Marine Statoo. The observations deal read that the staff of the Scottah Marine Statoo. THURSDAY, JUNE 25, 1891.

EDUCATIONAL ASPECTS OF FREE EDUCATION.

N innocent outsider would naturally suppose that the discussion on a proposal for free education would turn chiefly on educational and social considerations So long as the question was of merely academic interest, this was, to a large extent, the case. It is true that strong Churchmen viewed with distaste a change which might increase the growing difficulty, found by voluntary school managers, of making both ends meet, or might possibly even sweep them off the board altogether. and that the enthusiasm of many partisans on the other side for the remission of fees was heightened by the hope that such a measure would give a new impetus to the formation of School Boards But, on the whole, the disputants made at least an attempt in public to discuss the matter in its bearings on the child, the teacher, and the parent. The overburdened parent, the pauperizing effect of partial remission, the child kept from school because of his parents' poverty, the teachers converted into tax-collectors-these were the stage properties of the one party; while the stock-in-trade of the other side included the sacred necessity of guarding "parental responsibility," and the assertion that no one values what he does not pay for, and that to tax the hard-earned sayings of the respectable middle-class to free the education of the children of the worthless and unthrifty was a Socialistic proposal of the crudest kind.

We now find that most of this talk was pure cant It ceased to be heard from the moment when free education became a practical party question To outward appearance the contest over the Bill has become a kind of Terusalem race- everyone wishing to leave to someone else the unpleasant task of formulating the criticisms with which he secretly sympathizes, but to which fear of his constituents prevents him from giving utterance

If we could induce the parties to break through this conspiracy of agreement, we should find that, with a few exceptions, the point on which the advocates feel most keenly is the possibility of using the Act as a lever either to destroy or to perpetuate for ever the voluntary school system In spite of the apparent calm, the battle between the supporters of School Boards and voluntary schools is raging fiercely below the surface, and most of the amendments put down for the Committee stage are certain to represent attempts, more or less open or disguised, to wrest the provisions of the Act to suit the purposes of one or the other party.

It must be confessed that this is to a great extent natural. The Act of 1870 was a compromise; the present Bill virtually reopens the question, and it is felt that, whatever be the logic or want of logic in the argument that Imperial grants should involve local control, the time when large additional grants are being made to voluntary schools is the time, if ever, to drive home the question of popular management. We do not then. quarrel with those who feel that the opportunity must not be lost of raising this question; indeed, we should respect them more if they raised it more openly. But we do | Bill) should be also admitted free, or at least sufficient

protest against the almost total omission of all educational considerations in the arguments used on both sides.

It is time that the third party to the dispute-the real friends of education-made themselves heard. Their one object is to see that the educational benefits of the measure should be maximized, and the incidental evils minimized They ask what is to be demanded in the shape of increased efficiency in return for a new grant of (2,000,000 to school managers Is a great part of it to be allowed to be absorbed by the reduction of private subscriptions and rates, or is it to be used to improve the children's education, and make it a better preparation for their future industry?

In the rural districts, the grant in lieu of fees will almost universally be in excess of the income now received from fees There will therefore be a surplus in the hands of the managers, or manager--for very often these schools are in the hands of one man Where will this surplus go? In our opinion some method ought, if possible, to be found of "ear-marking" it for education rather than for subscribers' pockets. If this were done, nearly the whole of the rural schools of England might be raised in character It would be possible, for example, to introduce, with the aid of the new surplus, some simple teaching in agricultural subjects, such as is recognized in the Code. but is at present a dead letter, for the increased grant would be quite enough to pay a competent travelling teacher to give such instruction in a group of schools If there were universal county of district school authorities, it might be well to hand over the surplus grant into their hands, to be used solely for the improvement of the various schools on whose account it was paid. As, unfortunately, our organization is piecemeal, we are forced to deal direct with each school, and we can therefore only appeal to public-spirited managers to take care that the children for whose education they are responsible reap the full advantage of every penny which they receive over and above the present fees charged It is to be feared, however, that in many cases the managers are at the mercy of their subscribers, and many of them would probably now welcome the proposal made by the Bishop of London, but foolishly rejected by his clerical friends on the late Royal Commission -that a certain minimum of private subscriptions should be required by law in the case of every voluntary school. If such a provision were in force, school managers in the country would be saved many anxious forebodings at the present time

The second point in the Bill on which educational reformers should fix their attention is the limitation of the benefits to children between five and fourteen. The lower limit need not trouble us, and may be left to be worried by the "poor man's" numerous friends the upper limit should be resolutely opposed. quite true that at the present time it is of comparatively little importance-only affecting some few thousands of children But if one of the great objects of educational policy is to lengthen the period of school life, the handful of children at elementary schools above fourteen should certainly not be fined for staying there, if anything, they should receive scholarships to enable them to do so In our opinion, moreover, ex-seventh standard children (who are not for the most part touched by the present

scholarships should be provided to enable any poor child who has passed the standards to continue his education either in the school or elsewhere. We do not say that such scholarships should be universally provided out of the present grant, but they would be a most proper object to which to apply part of the surplus which will be handed to many schools over and above the fee equivalent. These considerations suggest another possible way of dealing with the surplus grants great object of those who are interested in the development of higher elementary, technical, and secondary education should be to strengthen instead of weakening the connection between primary and higher schools. It is to be feared that any provision for freeing elementary schools up to a certain point or a certain age, will tend to sever rather than to un to the two grades of schools, unless the flow between them is at the same time stimulated by the establishment of free scholarships or in other ways A free (or partly free) elementary school is not the ultimate ideal. We want a free road kept open to the University Is it too late to throw out the suggestion that school managers receiving a fee-grant in excess of the amount previously received in fees should be required to use the surplus for an object akin to that contemplated by the main provisions of the Bill-viz the extension of free education for selected scholars beyond the narrow limits of the primary schools, in other words the provision of continuation scholarships? Up to a short time ago it would have been replied that in many cases there were no higher institutions accessible, but the application of the Local Taxation grant to technical and secondary education is fast changing all that, and a proposal which a few years since would have been unfeasible is now well within the range of practical politics

DIFFERENTIAL AND INTEGRAL CALCULUS

Differential and Integral Calculus, with Applications
By Alfred George Greenhill, MA, FRS. Second
Edition (London Macmillan and Co, 1891)

PROF GREENHILL is known to the academic world as an accomplished mathematician who has powerfully helped to advance certain branches of applied mathematics, he is also known to the readers of N sturke as a friend (militaril) of the practical man. We say at once, in all sincerity, that we sympathize with Prof. Greenhill in both his capacities. The volume on the infinitesimal calculus now before us, although professedly a second edition, is in reality a new work, addressed to the special needs of the practical man by his mathematical friend Prof Greenhill.

of many of the author's didactic innovations we highly approve. The treatment of the differential and integral circliculus together from the very beginning is a piece of sound method, the introduction of which has been delayed method by the transpent practice of separating the two as examination subjects. The introduction of the hyperbolic functions to systematize the integrations which can be performed by means of the elementary transcendents, has been, as we can testify from experience, a great help in elementary teaching. The admirable "chapter in the mitegral calculus" which was sublished the marketive trin the mitegral calculus" which was sublished the marketive.

in an extended form some years ago, and is now condensed and simplified in a separate chapter at the end of the work under review, is the most important addition to the teaching material of the integral calculus that has been made for a long time; that chapter alone is worth the price of Prof. Greenhill's book. The plan of drawing the illustrations of the subject from departments of pure and applied mathematics with which the learner may afterwards have to do is also excellent. Finally, there blows through our author's pages that lnimitable freshness which emanates from the man who is familiar with much that is newest and best in his day, who does not merely make extracts from books, but who speaks of things in which he has taken a part. This freshness can only be compared to that agreeable odour which inland people tell us comes from mariners and others who cross the sea from strange lands. Like these same mariners. our author produces from his pockets strange and puzzling curiosities, such as recipiocants, tide predicters, Schwarzian derivatives, Mehler's functions, to delight and to dazzle the learner It is true he tells but little of these things, still, it is pleasant to look at them, and they make us happy under our present toil by leading us to think that we too may one day visit the country where these pretty things are at home amidst their proper sur roundings

Where there is so much to praise we are truly sorry to insinuate the bitter drop of blame, but, much as we love and follow Plato, something must be conceded to truth. In the first place, we think that in this second edition the introduction of heterogenuous illustration has been overdone. The fundamental rules of the infinitesimal calculus are really very few in number, and the practical man's friend would do well to impress that upon him at the outset, instead of scattering these principles through a large volume, and overlaving them with thick masses of disconnected application, to such an extent that poor Mr Practical-Man is in danger of losing his tools among the shavings, or, to use a metaphor which Prof Greenhill's pupils might prefer, of not seeing his guns for smoke Prof Greenhill must recollect that the man that sits down to read his book is not all possible practical menrolled into one, but one poor practical man-say, an engineer-who wants some knowledge of the infinitesimal calculus, and who will find many of the illustrations more indigestible than the principles of the calculus itself Would it not be better for the practical man, as well as for any other man, to have the few leading principles of the calculus set before him with an adequate but moderate amount of illustration of a uniform geometrical kind, and not to be dazed by a flood of oracular statements about soap-bubble films, tide-p edicters, &c , in the course of his initiation? Such digressions are most useful now and then in a lecture ; they serve to give picturesoneness to the discourse, and help to fix the attention of the hearer: but we think that too many of them destroy the usefulness of a text-book, the object of which is quite different from the purpose of a lecture

the hyperbolic functions to systematize the integrations which can be performed by means of the elementary transtendents, has been, as we can testify from experience, a
greathely in elementary teaching. The admirable "chapter in the misergal calculus" which was published separately |
s another matter, of more importance, on which we

would appeal to Prof Greenhill When a man, so able and unconventional as he, writes a book of 455 pages on the infinitesimal calculus, is it too much to expect that he will everywhere give a thorough discussion of its few fundamental principles, that he will rigorously prove what he professes to demonstrate, and honestly point out what he assumes without demonstration? We certainly expact him to root out of the subject every trace of the sham demonstration-that wilv artifice of the coaching and examining days of our dear old alma mater-which used sometimes to be dignified by the name of the "short proof" This used, to be employed when we had on hand the establishment of some proposition which was not universally time (although usually so enunciated), or which had exceptions too tedious to enumerate in an examination. The method was to make a kind of 6r6/15 containing as few words of intelligible English as possible, but a considerable sprinkling of ingeniously constructed but unexplained symbols and formula, so that an examiner of average conscience, suspecting that the truth was not there, might nevertheless, without mental distress, make believe that it was there, and award the coveted marks

We complain that Prof. Greenhill should countenance the slipshod exposition of elementary principles which is the bad feature of so many of our English mathematical text-books. Having started his furrow, he should have ploughed to the end. He may retort that he has adhered to the traditional usage out of consideration for the weakness of the practical man, who abhors sound logic quite as much as his academic brother Cruel consideration for the practical man for what he wants above all is a firm giasp of the furdamental principles of the calculus, he has rarely any use for the analytical house of cards, composed of complicated and curous formulac, which the academic type builds with such zest upon a slipper; foundation

It would take up too much of the columns of NATURE to give all the examples that might be adduced of the laxity we complain of A few must suffice. We are told in § I that the "calculus to be developed is the method of reasoning applicable to variable quantities in a state of continuous change," yet no definition or discussion of "continuity" is given . the word, so far as we can find, does not occur again in the first chapter, although it is the keynote of the subject. "Newton's microscope," for example, is quoted in § 9, as a proof of the theorem Lt(chord arc) = 1, but the essential condition, "in medio curvaturæ continuæ," which makes it a proof (if proof be the word that describes its purpose) is omitted. Although the differential calculus is merely a piece of machinery for calculating, and calculating with limiting values, a limiting value is not defined nor is there any discussion of the algebra of limiting values -- a matter which has puzzled beginners in all ages, and which has stopped many on the threshold of the calculus It is true that we are referred to Hall and Knight's "Algebra," but what we find there is little to the purpose, and certainly could never have been meant by its authors as a foundation for the differential calculus,

In § 16 we are given a quantity of elementary instruction, in the middle of which the trigonometrical functions are inadequately defined; but nothing adequate is said

regarding the sense in which the many-valued functions sin-1x, cos-1x, &c, are continuous and in § 25 the beginner is led by implication to believe that $d(\sin^{-1} i)/dv$ is always + $1/\sqrt{(1-x^2)}$, and $d(\cos^{-1}r)/dr$ always $-1/\sqrt{(1-x^2)}$; although this is not so, and the point is one that is of the greatest importance in the integral calculus, and is a standing rock of offence for learners In \$ 28 we have, reproduced "for the sake of completeness," the time-honoured "short proof" of the existence of the exponential limit, which proof is half the real proof blus a suggestio falsi. If the proper proof (a very simple matter) was thought too much for the reader, then it would have been better simply to tell him the fact, and not to corrupt his intellectual honesty by demanding his assent to a piece of reasoning which is not conclusive 8 31 is no better, what, for instance, does Prof Greenhill mean, after proving that $\exp n = \epsilon^n$, where n is a positive integer, by saving, "and thence generally by induction $\exp x = e^x$ for all values of t" It would scarcely be possible to write down a statement to which more excentions could be taken unless "induction" is a misprint for " assumption "

The chapter on the expansion of functions is not satisfactory. We are first introduced to "a general theorem. called Taylor's theorem, by means of which any function whatever can be expanded [in ascending powers of 1]" Prof Greenhill knows as well as we that there is no such theorem. No theorem ever to be discovered will expand in ascending powers of x, 1/x, 1/1, log 1, or any function Why does our which has x = 0 for a critical point author hide his light from the reader? Does it make the apprehension of Taylor's theorem any easier to enunciate it falsely? We are told in § 114 that "some functions, for instance sec-1x, cannot be expanded in an infinite series in ascending powers of r. because x must be greater than unity, and the expansion by Taylor's or Maclaurin's theorem would be divergent, and the theorem is then said to fail."

"This difficulty will be avoided if we can make the series terminate after a finite number of terms"

We would not advise the practical man to try to overcome the difficulty of expanding sec-ir by the method thus indicated (use of Maclaurin's theorem with the menander), because the result might be that the bond of annity struck in the preface between him and the authory would be broken. All the king's men will not get over this difficulty. Incidentally we are medial in State 1 and 1 and

When so many novelties of less importance are noticed, surely our author night have found a place for a reference to the theorem that puts the expansibility of a function in ascending powers of in histitue position, viii. Cauchy's theorem that every function is so expansible within a certain region surrounding i = 0, provided x = 0 to not a critical value. Considering the great unportance

of the fact, and its close connection with the applications of mathematics to physical problems, some mention might have been made of the importance of the critical points of a function in determining its value. A fall discussion of such things is doubtless impossible in an elementary treatuse; but the reader should at least be warred that what is given regarding the expansion of functions in power-senes is a mere fragment of what is known on the subject. The tendency of Prof. Greenhill's chapter on the expansion of functions creatingly will be to suggest to the mind of a beginner wrong general notions on the subject.

In § 126 we have two proofs given that

$$\partial^2 f(x, y)/\partial x \partial y = \partial^2 f(x, y)/\partial y \partial x$$

both of them insufficient, for the one rests on the assumption that f(x+h,y+k) can always be expanded in an integral h.k-power-series, the other on the assumption that

$$L L_{k=0} L_{\chi(h,k)} = L L_{\chi(h,k)},$$

both of which propositions are liable to exception

In the discussion of single and double integrals, no hint is allowed to reach the reader of the necessity of convergency as a condition of their having any meaning at all, of the precautions that must be observed in differentiating them, or in altering the order of integration. and so on Still, the reader is given a proof of Green's theorem What use this is likely to be to one ignorant of the fundamental character of the convergency and discontinuities of multiple integrals, upon which many of the most important applications of the theorem in question depend, it is not easy to see Too much of the work before us bears, in fact, the character of a hurriedly written précis or syllabus of lectures; witness, for example, the oracular character of §§ 146, 151, 152, &c. Our author makes enormous demands on the intelligence of a beginner if he expects him to follow and understand exposition so elliptical.

One more example of the thing we complain of. In § 18 we are introduced to Founer's sense No proof is given (none was to be expected in an elementary treatise) but it ought to have been stated that there are such conditions. Moreover, the method given for the determination of the coefficients is a mere memorial echonical for recollecting them It has no demonstrative force, because, as the atthor must be very well aware, it is not unconditionally allowable to replace the integral of an infinite sense (even if it be convergent) by the sum of the integrals of its separate terms In order that this may be admissible, the senses must be uniformly convergent.

Seeing that the world is very evil, and not to be mended in a day, we must put up with such things in the ordinary writer of English text-books, who caters for the victims of our manifold examinations. In but in a pillar of mathematical society like Prof Greenhill they are "most tolerable and not to be endured." A work with his name on its back, and the impress of his vigorous personality on its pages, will not remain long in a second edition. If he would be at once the frend of the practical man, and a well-deserver of the mathematical republic, let him, when the third edition is called for, reduce his elementary work to

the compass of the first edition or less, and replace all half demonstrations by honest statements of fact; and let him, meantime, write a larger work, to which he can refer the elementary reader who takes for his motto, G.C.

THE GEOLOGY OF THE COUNTRY ROUND
LIVERPOOL

Geology of the Country around Liverpool. By G. H. Morton, F.G.S Second Edition. (London . Philip and Son, 1891.)

N this work Mr. Morton has entirely re-written the "Geology of the Liverpool District," first published in 1863, by the light of the various discoveries made since that time, and especially of the Geological Survey maps and memoirs. He has succeeded in making a compact and well-printed hand-book, which will be of great service to the students of the local geology. The area described extends to about 20 miles from Liverpool on every side, excepting the sea on the west. The strata which he describes range from the Upper Silurians of the Vale of Clwyd through the Carboniferous, Permian, and Triassic rocks, down to the recent alluvia. To a geologist the chapter relating to the Carboniferous rocks of North Flintshire and the Vale of Clwyd will be of great interest, as it shows the thinning off of the strata as they approach the ancient Carboniferous land of North Wales Carboniferous Limestone, over 3000 feet thick in North Lancashire, is reduced to 1700 feet in North Flint and the Vale of Clwyd, while the Yoredales and Millstone Grits, over 9000 feet thick between Clitheroe and Burnley, are represented by the Cefn-y-Fedw Sandstone, 370 feet. The Lower and Middle Coal-measures, too, of South-West Lancashire, 3180 feet thick, have dwindled down to no more than 1000 feet as they approached the Welsh Silurian Hills It is therefore obvious that the Snowdonian area was dry land while the Carboniferous sea occupied the areas of Lancashire, Derbyshire, and Cheshire, and that it also overlooked the forest-covered morasses, now represented by the coal-seams of the same region in the Upper Carboniferous age. In the table of the rocks (p. 6) Mr Morton gives 300 feet as the thickness of the Millstone Grit in South-West Lancashire. It is probably much more than this, and not much less than 2000 feet Mr. Morton also, we may remark, understates the thickness of the Keuper Marls, which he puts down at 400 feet (p 75) In the Lancashire and Cheshire plain it is 700 + feet, and is estimated by Prof. Hull at 3000 feet

Mr. Morton, in dealing with the deep boring at Bootle, made in 1878, under the advice of the writer of this review, is mistaken in supposing that it was aimed at the water in the Perman Sandstone. It was intended to strike the water in the Lower Bunter Sandstones, and to draw upon the enormous area of water-bearing strata in the Lancashire and Cheshire plain, which have their outlet seawards between Prescot and the estuary of the Dee. It is very likely that the Permans are not represented under Liverpool. We expected to strike the Coal-measures at 100 feet. The sort figure from the geological and the engineering point of view. It proved that the Lower Bunter Sandstones below the top

of the Upper Pebble-beds are more than 1300 feet thick. and that they are highly charged with water. This thickness is altogether without precedent, and Liverpool is to be congratulated upon being built upon so great a thickness of water-hearing Triassic rocks. Mr. Morton, should the work reach another edition, would do well to deal at greater length with the water-supply available from the Triassic strata Mr. Boult has tabulated the well-sections, and all students of the geology of Liverpool would do well to examine his valuable tables

We would call special attention to Mr. Morton's section -unfortunately, the work is not divided into chapterson the origin of the estuary of the Mersey While the river has been draining its present watershed from a period far more remote than the Pleistocene age, he holds that the estuarine portion is comparatively modern, dating probably not further back than post-Roman times It would not, he argues, following Sir James Picton, have been neglected by the Romans, if it had then "presented the copious body of water which it does at the present day" There is no evidence that they did neglect it. The Manchester Ship Canal works have revealed the existence of Roman remains, probably the Veratinum of the anonymous geographer of Rayenna, on the banks of the Mersey close to Warrington, and Mancunium (Manchester) is on one of its tributaries. They used it, as they used all the rivers of Britain, for their own ends Deva (Chester), the great port, and military centre of the north-west, was not far off, and amply sufficient for the western trade at a time when there were no ports in Ireland. The commercial importance of the Mersey is solely due to the trade with the New World There was no reason why the Romans should have paid special attention to the estuary of the Mersey, and it was outside the system of their roads Nor can the date, 1279, of the great inroad of the sea over the Stanlow Marshes, by which the Abbey of Stanlow, built upon a rock only 28; feet above OD, lost much of its land, be taken as evidence of the modern formation of the estuary. The river swings to and fro at the present time, depositing silt here, and carrying away its banks there In our opinion, therefore, the post-Roman origin of the Mersey is not proved It is still less likely that it is the result of a local submergence, which has not affected Warrington and the adjacent area of Chester As the evidence stands, the date of the estuary of the Mersey belongs to the same remote prehistoric period as the estuary of the Thames and of the Humber-certainly after the time of the boulder clays, and probably long before there were any written records in Britain All three are later than the time of the submarine forest which, on the west of Britain. afforded shelter, not merely to our Neolithic ancestors, but to their domestic animals, such as the small shorthorn (Bos longsfrons), the goat, and the dog.

W BOYD DAWKINS

OUR BOOK SHELF.

Les Microbes, les Ferments, et ses Moistssures. Par le Dr. E L. Trouessart. Deuxième Edition. Bibliothèque Scientifique Internationale. (Paris, 1891.)

NO. 1130, VOL. 44]

first edition, give an excellent though short account of the morphology and physiology of fungi and of yeast Although chapter iii. (on bacteria) is enlarged, we do not think it is sufficiently up to date; thus, for instance, on pp 74 and 75, the author questions the existence of true flagella in bacteria, and states that their motility is essentially different from that of flagellate infusoria Again, in the section in which putrid decomposition is described no mention is made of the entire tribe of Proteus, the essential microbe of putrefaction.

Chapters iv and v. (pathogenic bacteria) are considerably enlarged, both as to text and illustrations The rest of the book, chapters vi -ix, does not differ in any essential

respect from its predecessor

On the whole, the book is very commendable as a concise text-book, well written and copiously illustrated, and as such deserves a high place in the literature of the subject

Botanical Wall Diagrams. Size 312 inches by 24 inches, printed in colours (London Society for Promoting Christian Knowledge, 1891)

A HERST instalment of six of these diagrams is now pub lished The plants illustrated so far are common elder, deadly nightshade, scarlet runner, hop, Virginia tobacco, and wild camomile We do not know on what principle the selection has been made. It is rather a pity that, out of so small a number, two (deadly nightshade and tobacco) belong to the same natural order, and show no very essential structural differences we hope that all the unportant orders will be re-presented. The drawings (executed by Engleder, of Munich) are quite artistic, and the colouring excellent The diagrams are thus very pleasing as pictures, and at the same time the botanical details are correct

If the series is continued as well as it has been begin, it ought to be a very useful help in the elementary systematic teaching of botany I) H S

Chambers's Encyclopædia New Edition Vol VII. (London and Edinburgh W. and R. Chambers, Vol. VII. Limited, 1891)

No one who has had occasion to refer to the new edition of Chambers's " Encyclopædia" can have failed to appreciate the care and ability with which it is being prepared The editor has been fortunate enough to secure the cooperation of many eminent writers, and the information given in the various articles, speaking generally, is well up to date and presented in the way most likely to be convenient for students. We are here concerned only with the papers on scientific subjects, and these, in the present as in the preceding volumes, are in every way worthy of the place which has been assigned to them in the scheme of the work as a whole Prof. P G Tait contributes a short but masterly paper on matter, and Dr. Buchan gives a clear and interesting account of The essential facts about the Mediterra meteorology ncan are compressed into very small space by Dr John Murray, who also writes on the Pacific Prof James Geikie deals with mountains and palæontology, and Dr Alfred Daniell has a good popular article on optics, devoted mainly to the history of optical science. In an article on man, Mr J. Arthur Thomson states very well some of the problems relating to human characteristics, the origin or descent of man, and the antiquity of the race: and the same writer sketches the career of Pasteur. and treats of mammals and parasites Municry forms the subject of an excellent paper by Mr. E B Poulton Of course, no subject is treated exhaustively, but the TRIS is not only an enlargement but a distinct improvement on the first edition. Chapters i and ii., as in the justification of the purposes for which an encyclopedia is

Glimbses of Nature By Andrew Wilson. (London Chatto and Windus, 1801)

MR WILSON does not profess to present in this book anything strictly new, or to give a full account of the various subjects with which he deals. Nevertheless, the volume may be of considerable value, for on all the groups of facts in which he is interested he is able to discourse brightly and pleasantly, and many of his short papers are well calculated to excite in the minds of intelligent readers a desire for more ample knowledge.
The papers are reprinted from the Illustrated London

LETTERS TO THE EDITOR.

The Fusing and Boiling Points of Compounds.

I HEREWITH send you the translation of a note just presented for me by M. Berthelot to the Parts Academy, as you may see in the ContMcs renduc. I have added two illustrations and a few words in italics St Louis, May 8. GUSTAVUS HINRICHS

Statement of the General Law determining the Fusing and Begling Points of any Compound under any Pressure, as Simple Function of the Chemical Constitution of the same by Dr. Gustawa Himrichs

The atomic form of normal lineary compounds, such as the paraffins, alcohols, acids, is very nearly prismatic. All other acrial compounds may be referred to these, either as isometics or

The boiling point f of a prismatic compound consists of two distinct functions, namely-

where
$$t = y_1 + y_2$$
 , , , (1)
 $y_1 = I_1(\log a + \log a_1)$, , (2)
and $y_2 = I_2(\log a_2 + \log a)^2$, , . . (3)

The symbols a_1 and a_2 represent certain definite values of the atomic weight a of the compound, while k_1 and k_2 are constants.

constants. For every value of the atomic weight a greater than a_1 the formula (1) is limited to $c = y_0$, which, according to (2), represents the straight line which I call the logarithmic limit, the ordinate being the boiling-point t, the alsociate x, the logarithm of the atomic weight $x = \log a$. For values of a less than the above limit a_p , the parabolic ordinate y_n determined by (3), must be added $t > y_p$. according to (1), in order to obtain the boiling-point.

bosing-posm.
Accordingly, the boiling point curve of any homologous series of prismatic atom-form consists of a parabolic arc (3), tangent to the logarithmic limit (3), 43 the point determined by a = a. The constant A, determines the inclination of the logarithmic limit, and A, may be called the parameter of the parabolic

Inarch.
All compounds derivable by terminal substitution from normal paraflats have a common logarithmic limit, determined by paraflats have a common logarithmic limit, determined by Every pubriculal homologous series of this great faithful of compounds a complexity determined by the special value of the companies, and \$\phi_p\$ for example, the charty-five normal reason of the properties tances are the head of the corresponding homologous series—that ii, H for the paraffins, H_0N for momentum, ii.

If now the co-ordinate $s = \log p$, where p is the pressure of

as substitution products The boiling and fusing points of these latter are obtained from those of the former according to laws latter are obtained from those of the former according to laws and processe pobls hed by me a vocat ventry years ago, partly in my. Principles, of Sulecular Mechanisms, partly and processe position of the processing of the done in an Assessation by the Advancement of Science for 1868. It remains, therefore, only to show how those fundamental points are determined for generated positions. pounds.

the saturated vapours, be laid off on the third rectangular axis the salarmen vapours, be that off on the third rectangular axis the above given values 1 elong to the plane XY determined by $\rho=760$ mm. For the pressure $\rho=15$ mm, the logarithmic limit is determined by $\lambda_1=517^{\circ}0$, and $\alpha_2=113.81$. If will be noticed that its inclination towards the X axis is less, and that it intersects the same at a greater distance from the origin. The logarithmic limit surface, generated by the log-authmic limits for all pressures, is a hyperbolic paraboloid, fully determined by the above two lines for 15 and 760 mm pressure. For any liquid, the absolute temperature T of the boiling under a pressure of p atmospheres is determined by the same general law slightly specialized as follows —

where
$$T = Y_1 + Y_2 \dots \dots (4)$$

 $Y_1 = K_1[1^*4 + \log p] \dots (5)$
and $Y_1 = K_2[\log \pi - \log p]^1 \dots (6)$

The logarithmic limits of all liquids astensed in the same absolute zero point determined by T=0=0=-27; C and $\log\rho=-1/4$. For each individual liquid this limit extends upwards to the critical point of the liquid, $\rho=\pi$ and $T=\theta$. For many liquids the critical point can be theoretically calculated, as well as the value of the parameter. It is understood

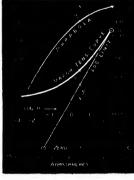

Fig 2.

that the parabolic curve is tangent to the logarithmic limit at i

It hardly needs to be said that the tension of dissociation, and even the solubility of solids, are subject to the same general law The fusing points are obtained by simply changing the sign

re obtained by simply changing the
$$l = r_1 - r_2$$
 (

so that the parabolic curve will be placed below the logarithmic

One of the most remarkable results of this research is the mechanical determination of the true position of the carbon atoms in organic serials, and the complete explanation of the difference in issuing point between compounds containing an even and old number of carbon atoms.

It should also be understood that the change in furing point produced by change in pressure is expressed by the same general

Name. Putting $\log a = v$, $\log f = z$, and $\log a = \xi$, $\log w = \zeta$, the formulæ (1) to (7) will become

These formulæ strikingly show the simplicity of the laws attacd, and also determine the surfaces formed by the coordinates x, t, and y in general.

In subsequent notes special topics covered by this general law will be taken up, and the complete concordance of the law with the results of observations will be shown.

Porpoises in African Rivers.

In reference to Mr Schäef's letter in NATURE of June II pr 124, the following may be interesting to your readers — The skull of a Delphionod Cetacean from Cameroon has tactly come and to my hands, through the kundress of Prof following information concerning if The animal to which it belonged was coaght in Knegachit By, after very heavy rains, and was being devoured by sharks. The contents of the stometon consisted of graw, weeki, and mangrove fruits. Note of the shark of the content of the stometon of th

Jam preparing for publication a detailed description of the Sull, and must here confine myself to emarking that, though the animal belongs to the genus Sulain, it differs in several secretal points from all the species of this genus binetro idesected properties of the second properties of the twenty-seven teeth on each side in each juw. Their form, in that they are no pointed, but word own, indicate, as is so do the contents of the stomach, that the animal is herbivorous. It would be supported to the summer of the summer of the word known that other Souliai live in rivers.

Jena, June 20 WHITE KUKENTHAI

PHYSICAL SCIENCE FOR ARTISTS.

I HINK it right that I should begin by explaining how it is that I am here to-day, to lecture to you on a subject which touches art as well as science. It happens in this wise. Some years ago, while studying a certain branch of optics, it became important for me to try to summer and its student of the property of the

My friend, and your friend, Dr Russell, happens to know this little bit of my experience, and hence it has less is that he requested me to come down to-day to say a few words to you, his plea being that this College is one of the very few institutions of its kind in the world where there is a studio and a physical laboratory side by side.

That, then, is the reason I am here, and what I want to impress upon you to-day is that the highest art can only be produced by those who associate the study of physical science with the study of art, and that therefore the possible producers of the highest art can only be looked for in such an institution as this if training of any kind has anything to do with it.

*A Letture delivered at Bedford College, by J. Norm in Lockyon, F.R. S. on June to, 1991

I think that the general conditions of art training as they exist at present absolutely bar any sufficient know-ledge of the laws and conditions of natural phenomena

on the part of art students

The best art of the time has always been on a level with the best science of the time, and if it had not happened that the first schools and the first Universities clustered round medical schools and schools of anatomy. I do not think that so much attention would be given to-day to anatomical science to the exclusion of all other branches.

You see, then, it comes to this. It is conceded by the art world that in a certain direction the phenomena of Nature require to be studied, otherwise that tremendously exuberant literature on Anatomy for Artists would not have been written, and more than half of the time of students of art would be spent in studying something else rather than those things which they do study
It is on that ground that I would venture to say that in

other institutions, as in this one, the study of physical science should be added to the other branches already

recognized by the art world

l am not an artist I am not an art critic I am almost unacquainted with the language usually employed by those who write on art subjects. I shall not deal with opinions, the algebraical sum of which in relation to the qualities of any one picture I have often noticed is zero; but what I shall try to do is to stick as closely as I can to the region of fact, and endeavour to show you, by two or three individual instances, how a student who wishes to become a great artist- as some of you no doubt dowill find his or her ambition more likely to be realized if the study of physical science be combined with that of "Art as she is taught" to day.

In looking at the Academy Catalogue this year one finds the motto, "La mission de l'art n'est pas de copier la nature, mais de l'expiriner," and this is a true motto But let us analyre it a little To "express" suggests a language; a language suggests a grammar, if it is to be perfect, satisfying But what can this grammar be, in the case we are considering, but the laws underlying the phenomena the "expression" of which, in his own language, constitutes the life-work of the artist Should he be content to show himself a bumpkin? Are solecisms to be pardoned in his expressions because, so far, scientific training and thought are so limited? Is he justified in relying upon the ignorance of mankind, and, if so, is the highest art always to remain divorced from the highest knowledge?

Now it so happens that the branch of physical science which is above all things the thing to be studied by artists, is the branch of it which is already familiar to you—namely, optics. There could be no art without light; no artists without light, and the whole work of an artist, from the beginning to the end of his life, is to deal with light Now we live in a world of white light. We might live in a blue world, or a green world, and then the condition of things would be different, but we can, in our laboratory, make our world red or green for the moment, but some-times, indeed, when we do not seek to make this experiment, we find the world changed for us by the means which we employ for producing artificial lights, such as candles, gas, or the electric light, since in these, colours are not blended in the same way as in a sunbeam

We thus come to the question of the radiation of light, and the way in which this light, whatever its quality, is re-flected by natural objects, it is by this reflection that we see them Everything that an artist paints which is white, is painted white by him for the simple reason that it reflects sunlight complete. It is perfectly clear that any reflecting surface can only reflect the light which at rehave red walls and green trees; the direction of the light is not changed, except in the way of reflection, and you are already acquainted with the imperative law of optics -that when light falls upon a body and is reflected, the

angle of reflection is equal to the angle of incidence.

To us this drastic law is of the very highest interest. We can apply it to art in a great many ways, but I will only take two very simple ones. Oftentimes it is our fortune to be in the country by the side of a river, or at the seaside. In both cases we see things reflected in water, and at first sight it would seem that here the artist ought to find perfectly free scope, but the worst of it is that, though he has free scope, sometimes his on it is that, though he has free scope, sometimes his picture becomes very unpleasant to people who are acquainted with the law! I have stated 1 find here some diagrams, prepared by the kindness of some of our friends, which will show you the intimate connection between art and science in this direction. In the pictures which you will see in the Royal Academy and the New Gallery, I fancy you will see some which, if you care to study them from this point of view, will be found not to agree with the law

In the diagrams we have a surface of water and observers at the top and bottom of a cliff. We have on the other side of this surface of water a tree Now, what anyone would do who disdains to "copy" Nature, and who paints without thinking, is this he would paint what he saw on the bank, and then turn it upside down and paint it again But you see that will not do, because the conditions are as you see them here. The higher spectator, No 1, the angles of incidence and reflection being equal, although he can see the upper part of the tree and part of the trunk, will not be able to see it all completely reflected in the water. You see that the lower part of the tree cannot be seen in the reflection, because any light reflected by it first to the water and then to the eye is really cut off from the eye of the spectator by the bank; if you greatly vary your distance from the other side of the water, you will find the reflection as represented in the other diagram Now, to anyone who has studied optics, if such a matter as this is represented wrongly in a picture, it becomes an intolerable nuisance, and when you go away you feel sorry that the artist did not do justice to what he wished to represent A good example of truth to Nature in this respect is to be seen at the German Exhibition-No. 205-in one of the landscapes, which I saw last night, it is a beautiful instance of careful study, and is absolutely true in this respect. The artist has shown liow a lutely true in this respect mountain side, with high lights upon it, reflected on the surface of a lake, appears very different in the reflection, in consequence of an intervening elevation near the edge of the water When you have thought out the difference of the appearances on the lake and on the hillside, you will appreciate the truth and skill of the artist enormously

Another serious fault arising from the neglect of this same law is to be found in very many pictures in which we get the reflection of the sun or moon in water

Obviously, if the water is disturbed, the reflection upon the water must depend upon the direction of the disturbance I need not say more than that to you You will quite understand what I mean, but if you look at the pictures in the Royal Academy this year—Nos. 677, 1071, and 1155—you can see how very admirably this reflection can be rendered; and if you look at 165 and think the conditions out, you will wonder how the artist should trouble to paint something that is absolutely opposed to the physical law.

opposed to the physical law.

You know that, in those instances where you get a
natural reflection, if the light source be beyond the object
which reflects the light, the nearer it is in a line with it
the more light will be reflected. You see that that rule relates to almost every landscape or seascape that is painted, for the reason that our air is filled with particles which reflect light. If it were not so, our atmosphere would be absolutely black.

It therefore follows that the light of the sky must increase in intensity as the sun or moon is approachedthat is to say, in a sun-setting or moon-setting, if you paint an unbroken sky, there must be an increase of intensity towards the light source. I am almost ashamed to make such a statement, because it is so obvious to you as students of science, but to the artist who is not a very service observer, why should it artible him! The fact strict observer, why should it artible him! The fact you study the pictures Nos. 650, 580, 1444, in the Royal Academy, and No. 39 in the New Gallery, you will find there indications of a neglect of this law. Now the sky is far more luminous than it ought to be by the light indicated by the landscape. Again, the setting sun is not so bright as the clouds which it is supposed to fluminate, too indicated, and, if anything, the sky is rather less luminous where the sun is than further away!

A good rule, and one which a student of physical science would be ceitain to act upon with considerable care, would be never to show anything as reflected which

An interesting example of this kind was exhitted in the Academy some years ago! Is so happened that a French man of science wrote a book on physical phenomen, beautifully illustrated. Among the illustrations was a coloured copy of a photograph of a soap bubble was bordy in the Collège de France, in which the photograph was taken, was, like yours, very well lighted by many windows, and the soap bubble was blown in the middle of it. A translation of this book appeared in English, and the illustrations were reproduced.

An artist had a most excellent idea. He thought he would paint a picture of a garden, which he did admirably. The foreground looked bare, so he thought he would put children playing in it. It next struck him, with the properties of the picture of

Then, again, an the matter of reflection, it would not be right that I should fall to remind you that, besides things terrestrial, we have the moon, which rules the inght, and rules the night because it reflects the smulght to us. Now, in a little talk like this I must not take up much time with astronomy, but it is fortunate that books on astronomy can be got for 6d or is which will tell us, which we made consider in the present connection. The moon is lighted by the sun. The sun can only light one half at a time. If we are on the side of the moon which is lighted by the sun, we must see the complete lighted half which we call a full moon. If we see a full moon, we must have our back to the sun. If we see a full moon, we must have our back to the sun. When the position of the moon with reference to the earth is such that we can that the can the sun is lighted up.

But none of these things are so in art. Last year a picture in the Academy was absolutely disfigured by the dark part of the moon being turned to the sim. Surely twin sort worth the artist's while to paint a moon if he tidd not know how to do it. But the moon has been the properties of the similar to see it the moon was right. I went and saw the picture, and had to say that the moon was saw the picture, and had to say that the moon was saw the picture, and had to say that the moon was saw the picture, and the similar that the picture was some similar to the similar to t

must be full. My friend said to me he knew this, and that as a matter of fact the arist had painted a full mono to start with, but he had altered it because it "destroyed the balance of his picture." That you see was where art came in. And then he added to stone the stone of the picture of the picture, and that stone it stone

I am sure that the students of this College will know that such things as these are to be avoided, even if there were difficulties caused by the non-existence of a book on astronomy. No artist need paint a moon in a picture

if he be too ignorant to paint it properly

Everything that you paint in a picture, which you paint because it reflects light, should be painted its proper size in relation to the other objects. It seems, however, that the moment a body which reflects light does not happen to be on the surface of the earth, you may, in art, make it as large as you please. I do not think that the monn's distance from the earth gives us any right to treat it in this way.

An eminent American astronomer some years ago looked at the pictures in the New York galleries from this point of view. The moon subtends a certain angle Everything else in a picture can be expressed in this way the moment you put a moon into! This astronomer took the trouble to get out, a statistical table of the did the picture of the country of the picture of the country of the picture of the country of the picture of t

Next, permit me to xay a few words on another point, in order to show that the student of art will delight more and more in his work as he or she knows more and more of refraction can be divided into deviation and dispersion. The phenomena of deviation tack dispersion. The phenomena of deviation teach us that when a heam of light, whatever its colour, passes out of one medium into another its course is changed. An experiment, which is easily performed and which is more a home-experiment to look over the edge in such a direction that the coin is just invisible then fill it with water, the coin appears Another experiment is to insert a straight body, such as a pencil, into this bowl of water it appears to be broken; a pencil, which is bowl of water it appears to be broken; really is if you look at 1004, you will find that this deviation has been made to act the wrong way.

It is rather a bad thing to attempt to paint a nymph partly in and partly out of clear water, because her body, if the picture be truly painted, would follow suit with the pencil

Passing from deviation to dispersion we come to ranbows. You have learned, and perhaps seen demonstrated by experiment, that we deal with a beam of white light coming from the sun and refracted at the front surface of a ran-drop. It is next reflected and again refracted down to the eye, so that the eye sees a bow, with all the spectrum colours due to the dispersion. If the light be strong enough, we get what is called a supplementary bow, and, in consequence of internal reflections, the two reds are brought together.

The point is that in this dispersion, brought about by the rain-drops, the effect is produced in a plane passing through the sun, your eye, and the rain-drop; your eye being in the centre, so that if you see a rainbow at all, you must have your back to the sun. The bow is always circular, and high or low according to the height of the

sun. Those are, of course, conclusions which a very restricted study of physical science will make perfect clear: why you get the two reds together when two bows are evisible; why the blue is made, and the red outside the single bow, also follows from a demonstration study to the study of the study of the study of the from a book. The main point is that a rambow is produced by a physical cause, so that, if you once grasp the idea of the cause of a rambow, its whole anatomy will remain for ever with you.

"It is qu'ils impossible for you to see a rambow in prosective, or projected on the ky as an ellipse. That will be quite clear, I think. Still, both these are recogniced arrobects. I am solry to hay that in this year's Academy there is one case in which you will find that the fundamental condition of having your back to the hot. 35 a most resultant to the property of the think of the control of the property of the control of the property of t

(To be continued)

THE FARADAY CENTENARY

ON Wednesday, June 17, at the Royal Institution, Lord Rayleigh delivered a lecture in connection with the hundredth anniversary of Faraday's birth. The Prince of Wales presided.

Lord Rayleigh said that the man whose name and work they were celebrating was identified in a remarkable degree with the history of that Institution if they could not take credit for his birth, in other respects they could hardly claim too much. During a connection of fifty-four years, Faraday found there his opportunity, and for a large part of the time his home. The simple story of his life must be known to most who heard him. Fired by contact with the genus. of Davy, he volunteered his services in the laboratory of the Institution. Davy, struck with the enthusiasm of the youth, gave him the desired opportunity, and, as had been said, secured in Faraday not the least of his discoveries The early promise was indeed amply fulfilled, and for a long period of years by his discoveries in chemistry and electricity Faraday maintained the renown of the Royal Institution and the honour of England in the eye of the civilized world. He should not attempt in the time at his disposal to trace in any detail the steps of that wonderful career. The task had already been performed by able hands. In their own Proceedings they had a vivid sketch from the pen of one whose absence that day was a matter of lively regret. Dr. Tyndall was a personal friend, had seen Faraday at work, had enjoyed opportunities of watching the action of his mind in face of a new idea. All that he could aim at was to recall, in a fragmentary manner, some of Faraday's great achieve-ments, and if possible to estimate the position they held in contemporary science Whether they had regard to fundamental scientific

monetar to y man regent to indicate the summer of the control of t

that Faraday's discoveries were so fundamental as to have become familiar to all serious students of physics. The first experiment required them to establish in one

coil of copper wire an electric current by completing the communication with a suitable battery; that was called the primary circuit, and Faraday's discovery was this:
That at the moment of the starting or stopping of the
primary current in a neighbouring circuit, in the ordinary sense of the words, then completely detached, there was a tendency to induce a current. He had said that those two circuits were perfectly distinct, and they were distinct in the sense that there was no communication between them, but, of course, the importance of conducting the experiment resided in this—that it proved that in some sense the circuits were not distinct; that an electric current circulating in one does produce an effect in the other, which is propagated across a perfectly blank space occupied by air, and which might equally well have been occupied by vacuum. It might appear that that was a very simple and easy experiment, and of course it was so in a modern laboratory, but it was otherwise at the time when Faraday first made it With all his skill, Faraday did not light upon truth without delay and difficulty. One of Faraday's biographers thus wrote—"In December 1824, he had attempted to obtain an electric current by means of a magnet, and on three occasions he had made elaborate and unsuccessful attempts to produce a current in one wire by means of a current in another wire, or by a magnet He still percurrent in another wire, or by a magnet He still per-severed, and on August 29, 1831—that is to say, nearly seven years after his first attempts-he obtained the first evidence that an electric current induced another in a different circuit" On September 23rd, he writes to a a different circuit." On September 23rd, he writes to a friend. R Phillips "I am busy just now again with electro-magnetism, and think I have got hold of a good thing, but cannot say, it may be a weed instead of a fish that, after all my labour, I at last haul up." We now know that it was a very big fish indeed Lord Rayleigh proceeded to say that he now proposed to illustrate the mechanics of

the question of the induced current by means of a model (see figure), the first idea of which was due to Maxwall. The one actually employed was a combination known as Huygen's gear, invaried by hum in connection with the winding of clocks. Two similar pulleys, A, B, turn upon a piece of round steel fixed horizontally. Over these is

hung an endless chord, and the two bights carry similar pendant pulleys, C, D, from which again hang weights, E, F. The weight of the cord being negligible, the sys-tem is devoid of potential energy; that is, it will balance, whatever may be the vertical distance between C and D. Since either pulley, A, B, may turn independently of the other, the system is capable of two independent motions.

If A, B turn in the same direction and with the same velocity one of the pendant pulleys, C, D, rises, and the other falls. If, on the other hand, the motions of A, B are equal and opposite, the axes of the pendant pulleys and the attached weights remain at rest. In the electri-cal analogue the rotatory velocity of A corresponds to a current in a primary circuit, that of B to a current in a secondary. If, when all is at rest, the rotation of A be suddenly started, by force applied at the handle or otherwise, the inertia of the masses E, F opposes their sudden provement, and the consequence is that the pulley B turns backwards, s. e. in the opposite direction to the rotation imposed upon A. This is the current induced in a secondary circuit when an electromotive force begins to act in the primary In like manner, if A, having been for some time in uniform movement, suddenly stops, Il enters into motion in the direction of the former movement of A. This is the secondary current on the break of the current in the primary circuit It might perhaps be supposed by some that the model was a kind of trick Nothing could be further from the truth. The analogy of the two that precisely the same argument and precisely the same mathematical equations proved that the model and the electric currents behaved in the way in which they had seen them behave in the experiment. That might be considered to be a considerable triumph of the modern dynamical method of including under the same head phenomena the details of which might be so different as in this case. If they had a current which alternately stopped and started, and so on, for any length of time, they, as it were, produced in a permanent manner some of the phenomena of electrical induction, and if it were done with sufficient rapidity it would be evident that something would be going on in the primary and in the secondary circuit The particular apparatus by which he proposed to illustrate those effects of the alternating current was devised by a skilful American elec-trician, Prof Elihu Thompson, and he had no doubt it would be new to many. The alternating current was led into the electro-magnet by a suitable lead; if another electric circuit, to be called the secondary circuit, was held in the neighbourhood of that, currents would be induced and might be made manifest by suitable means. Such a secondary circuit he held in his hand, and it was connected with a small electric glow lamp. If a current of sufficient intensity were induced in that secondary of sufficient intensity were induced in that secondary circuit it would pass through the lamp, which would be rendered incandescent [illustrating] It was perfectly clear there was no conjuring there, the incandescent lamp brightened up. One of the first questions which presented itself was, what would be the effect of putting something between Experimenting with a glass plate, the properties of the present copper plate the lamp went completely out, showing that the copper plate was an absolute screen to the effect, whatever it might be Experiments of that kind, of course in a much less developed and striking form, were made by Faraday himself, and must be reckoned amongst some of his greatest discoveries

Before going further, he might remark on what strong evidence they got in that way of the fact that the propagation of the electric energy which, having its source in the dynamo downstairs, eventually illuminated that inthe lamp, was not merely along the wires, but was capable of bridging over and passing across a space free from all conducting material, and which might be are; glass, or;

equally well, vacuum Another kindred effect of a striking nature, devised by Prof. Elibi Thomson, consisted in the repulsave action which occurred between the primary current circulating around a magnet and the current induced in a single hoop of aluminum wire. Illustrating this by experiment, he showed that the repulsave was to be a single for the property of the

About the time the experiments of which he had been speaking were made, Faraday evidently feit un-easiness as to the soundness of the views about electricity held by his contemporaries, and to some extent shared by himself, and he made elaborate experiments to remove all doubt from his mind. He re-proved the complete identity of the electricity of lightning and of the electricity of the by words which might convey a meaning beyond that which facts justified. Much use was made of the term "poles" of the galvanic battery Faraday was farad of the meaning which might be attiched to the word pole," and he introduced a word since generally substituted, "electrode," which meant nothing more than the way or path by which the electricity was led in the way or path by which the electricity was led in dangerous, as meaning more than they really knew about the nature of electricity, and was remarked by Maxwell, Faraday succeeded in banishing the term "electric fluid" to the region of newspaper paragraphs.

Diamagnetism was a subject upon which Faraday worked, but it would take him too long to go into that subject, though he must say a word or two found that whereas a ball of iron or nickel or cobalt. when placed near a magnet or combination of magnets, would be attracted to the place where the magnetic force was the greatest, the contrary occurred if for the iron was substituted a corresponding mass of bismuth or of many other substances. The experiments in diamagnetism were of a microscopic character, but he would like to illustrate one position of Faraday's, developed years after-wards by Sir Wm Thomson, and illustrated by him in many beautiful experiments, only one of which he now many occurring experiments, only one of which ne now proposed to bring before them. Supposing they had two magnetic poles, a north pole and a south pole, with an iron ball between them, free to move along a perpendicular line, then, according to the rule he had stated, the iron ball would seek an intermediate position, the place at which the magnetic force was the greatest. Consequently, if the iron ball be given such a position, they would find it tended with considerable force to a central position of equilibrium; but if, instead of using opposite poles, they used two north poles, they would find that the iron ball did not tend to the central position, because that was not the position in which the magnetic force was the greatest. At that position there was no magnetic force, for the one pole completely neutralized the action of the other. The greatest force would be a little way out, and that, according to Faraday's observations, systematized and expressed in the form of mathematical law by Sir Win Thomson, was where the ball would go This was illustrated by experiment.]

The next discovery of Faraday to which he proposed to call attention was one of immense significance from a scientific point of view, the consequences of which were not even yet fully understood or developed. He referred to the magnetization of a ray of light, or what was called

in more usual parlance the rotation of the plane of polarisation under the action of magnetic force. It would be hopeless to attempt to explain all the preliminaries of the experiment to those who had not given some attention to those subjects before, and he could only attempt it in to those subjects before, and he could only attempt it in direction perpendicular to that of the ray of light By experiment he showed that the polarization which was suitable to pass the first obstacle was not suitable to pass the stored, but if by means of any mechanism they turn round the vibration, they would then give it an opportunity of passing the second, but if by means come of any mechanism they turn round the vibration, they would then give it and turn round the vibration, they would then give it and what was involved in Faraday's discovery [Experiment]. As he had as also, the full agenticance of the experiment however, was contained in the observation of Sir William Thomson, that the rotation of the plane of polarization proved that something in the nature of rotation must be going on within the medium when subjected to the magnetism gforce, but the precise nature of the rotation not be known for some time to come.

When first considering what to bring before them he hought, perhaps, he might include some of Faraday's acoustical experiments, which were of great interest, though they did not attract so much attention as his fundamental electrical discoveries. He would only allude to one point which, as far as he knew, had never been noticed, but which Faraday recorded in his acoustical papers. "If during a strong steady wind, a smooth flat sandy shore, with enough water on it, either from the hought of the strong which was not been sometimed to the consideration of the strong which is not to form wases, he observed in a place where the wind is not broken by pits or stones, stationary undulations will be seen over the whole of the wet surface

... These are not waves of the ordinary kind, they are (and this is the remarkable point) accurately parallel to the course of the wind. When he first read this statement, many years ago, he was a intiel doubtful as to make the possibility of the papears to the statement of Paradoy words. He knew, the appearent to the parallel words the possibility of waves of that kind being generated under the action of the wind, and it was, therefore, with some curonst that two or this eyes ago, at a French watering-place, he went out at low tide, on a suitable day watering-place, he went out at low tide, on a suitable flay words and the statement of the could be considered to the statement of the possibility of the poss

Many matters of minor theoretic interest were deast with by Faraday, and reprinted by him in his collected with by Faraday, and reprinted by him in his collected lamentable accident which occurred owing to the breaking of a parafini namp. Faraday called attention to the fact, though he did not suppose he was the first to notice it, that, by a preliminary preparation of the lungs by a number of deep inspirations and expirations, it was possible so to acreate the blood as to allow of holding the breash for a acreate the blood as to allow of holding the overship of a scratch that the collection of the control of the collection of the col

The question had often been discussed as to what would have been the effect upon Faraday's career of discovery had he been subjected in early life to mathematical training. The first thing that occurred to him about that, after reading Faraday's works, was that one would not wish him to be anything different from what he was. If the question must be discussed, he supposed they would have to admit that he would have been saved much wasted labour, and would have been better en rapport with his scientific contemporaries if he had had elementary mathematical instruction. But mathematical training and mathematical capacity were two different things, and it did not at all follow that Faraday had not a mathematical mind Indeed, some of the highest authorities had held (and there could be no higher authority on the subject than Maxwell) that his mind was essentially mathematical in its qualities, although they must admit it was not developed in a mathematical direction. With these words of Maxwell he would conclude. "The way in which With these words Faraday made use of his idea of lines of force in coordinating the phenomena of electric induction shows him to have been a mathematician of high order, and one from whom the mathematicians of the future may derive valuable and fertile methods"

THE ROYAL NAVAL EXHIBITION.

THE Naval L-vhbition, now being held at Chelea, is distinctly a popular show. The management—recogning that the first duty of an Exhibition is not to show a pecuniary deficit—line wheely decided to follow the lead given by Sir Philip Cunliffs Owen, and has perpendicular to the properties of the properties of the properties of the properties of a kind known to salors as "improngs". The end justifies the means. Not only does the Committee of distinguished Admirals labour to supply Londoners with a cheap and innocent albour to supply Londoners with a cheap and innocent description of the properties of

The Exhibition appears to be divided into about half-acores sections, each under the direction of a committee Of these the "Entertainments" and "Refreshments" Committees appears to be the one which has made the most mittee appears to be the one which has made the most logical sequence. In the Septings Callery here is a collection of models of warships illustrating the progress of naval architecture, from the Great Harry of down to the very latest design of armour-chad battleship. The model of the Great Harry is of very doubtful authenticity, and is of modern construction, having been made to shape a ceast. No historical collection of British warships would, however, be even approximately complete without a representation of this vessel. Charnock, our great sauthority on the subject, has styled her "the presentation of this vessel. Charnock, our great sauthority on the subject, has styled her "the presentation of this vessel. Charnock, our great sauthority on the subject, has styled her "the could be, otherwise than by the and of oars, taken to the quarter from which the wind was blowing. It must have seemed a great feat in those days—little less than necro-many. Portunately for the timed intellecture as a more many. Portunately for the timed intellects of our rounded bulls, high topsides, and currously rigged craft rounded bulls, high topsides, and currously rigged craft could not have sailed more than a point or two to wind-

ward. Still, it was the Great Harry, or one of her comtemporaries, by means of which his new feature in seamanship was inaugurated; a feature by which the great middle period in the world's history of naval warfare was created, and which enabled the sailors of those times to make a dintrict advance upon the lessons taught them by their inand Standinavians. It would have been well if we had improved on our predecessors in other nautucal matters as well; and we then should not have had, even in the present century, our shipurpights attaching lead sheathing to ships' bottoms with iron mails. The Romans used and of their weeken they feat covered the under-vater

There are but three models of seventeenth-century ships in the Exhibition, but one of these is a vessel that forcibly illustrates, by contrast, the mutability of the present age. The Royal William was designed by the first great naval architect, Phineas Pett—whose name might almost more appropriately have been given to the Models Gallery than that of Seppings -and was built at Moders Callety from that of Seppings—and was outlety from that of Seppings—and was outlet Catalam in 1670. She was onginally a three decker, carrying one hundred guns, but in 1757 she was cut down to a ship of 8 guns, and was finally broken up in 1813—A fact duly recorded by the present Director of Naval Construction, Mr. W Hw White, in his delightful lecture on "Modern War Ships," delivered a few years ago at the Manson House "The Royal Wildhum must not, however, be taken as an example of the endurance of ancient materials so much as of the slow changes in design which characterized the proceedings of our ancestors The original material part of the Royal William only lasted twenty-two years, for she was rebuilt, we are told, in 1692, and again in 1719; so that in this respect she compares unfavourably with so modern a vessel as our first ironclad, the Warrior, which has only recently been taken out of the Navy after a service career of not far from 30 years Even now the Warrior has not been removed from the Navy list because she has become worn out, but simply because she has become obsolete If we could reach finality in design—if the inventive brain would reach thanky it design—it the inventve blain would stagnate—there is no reason why the modern iron-built warship should not outlast its wooden predecessor by almost as great an extent as it exceeds it in power of destruction. It is true the natural life of the old ships was a long one The Victory was forty years old when she was engaged in the battle of Trafalgar, and had seen much active service, having been launched at Chatham in 1765, but then she had been laid by as worn out in 1801, and it was only after extensive repairs that she was made fit for sea. A year or two ago, it will be remembered, she was found to be so rotten that she would have sunk at her moorings had she not been taken into dock and in part rebuilt. On the other hand, there is no reason why an irro ship should not last, provided she were properly painted and kept up, perhaps until the era when warships will have become relics of a barbarous past. The expression "properly painted" must be here taken in its literal sense; and with regard, to steel ships due steps must be followed to remove mill-scale, a precaution which has not always been taken of late, as quite recent mishaps have testified

Tassing from hulls to motive power, we find the same Passing from hulls to motive power, we find the same permanence of design more strongly emphasized in the practice of to-day compared with that of the naval era which closed with the introduction of steam and iron bulls. With comparatively small variations in detail the rig of war ships has remained unchanged from the days of Pett down to those within the memory of men still luving. The Henri Graze & Dieu shows a distunctly mediaval rig callhough her fighting-tops are ridiculously like those of our very latest armour-clads—but it would take almost a sallor's get no joint out the differences in said play between

Vandevelde's beautiful painting of the Sovereign of the Seas, "built in 1637," and the ships which appear on the canvases of Stanfeld, Turner, and Cooke. So much for permanence of design with masts and sails; with the succeeding mode of propulsion, engines and boilers, we find as striking a result in the opposite direction Steam machinery was first introduced into the Royal Navy in small gun boats, and later in the paddle-wheel frigates, but it was not until the screw was proved to be the more effective instrument that even the most sanguine engineers could hope that engines and boilers would successfully rival masts and sails as a means of propulsion. We pass over, therefore, the unimportant era of paddle-wheels, but even taking screw engines alone we find that during the last forty years far greater changes have taken place in the design of steam machinery than characterized the arrangement of masts and sails during the two hundred years elapsing between the time the Sovereign of the Seas was built and the practical introduction of steam into the Navy, indeed we might, without any great fear of contradiction, go further and say that to the eye of the engineer there is no greater affinity between the screw engines of forty years ago and those of the present day. than existed between the rigging of the ships of the Norse sca-kings and those of almost our own day, putting on one side only the element of size. The collection of engine models in the Exhibition is far from complete, and is not to be compared with that of ship models. There is a good reason for this, as engineers work to drawings, and models are seldom made excepting as records; whilst their cost is so great as to render them available only for very rich firms The collection of models shown by Messrs. Maudslay, Sons, and Field constitute the greater part of the historical collection in the Exhibition liere may be seen representations of the first types of incre may us seen representations of the first types of steam-engine introduced into the Navy, and we think a comparison of the early engines in this collection with, say, the magnificent model of the Subacyast engines, shown by Messri Hawthorn, Leslie, and Co, will bear out the remarks we have made. What path the progress of marine engineering will follow in future it is difficult to forecast The inventions of to-day always seem to have reached finality, but it is difficult to imagine that any fundamental change can be effected so long as we retain the use of steam as a vehicle for the conversion of heat into work. It may be that a little engine shown in the Exhibition - Priestman's oil engine - may contain the germ of a principle upon which marine engines may be designed in future, and that before we have got far into the twentieth century the marine boiler, with all its costliness and complication, may have become as much a relic of the past as the pole masts and uncouth sails of the Great Harry. Before that time arrives, however, the four-stroke cycle will have to be superseded

"It is, however, the steam boiler, rather than the engine, which has governed the design of ship machinery Fortyto forty-five years ago, steam pressures were not generally higher than 5 to 8 pounds per square inch. With the introduction of tubes in place of flues, which took place between 1840 and 1850, the working pressure rose to 15 pounds per square inch. The square box business and use, and with think per square loss higher than 1840 and 1850, the working pressure rose to 15 pounds per square inch, or not much beyond, unless the staying of the flat suifaces was carried to an undestrable extent. With such a limit of pressure, the simple expansion engine was, properly, the usual type, but when the cylindrical manne boiler was introduced, the average steam pressure quickly note to 60 pounds to the square inch, and the compound engine accessary part of this step in advance, for, with the higher temperature due to the increased steam pressure, it was impossible to pass large quantities of salt water through the boilers without rightly scaling them up. For some time the

difficulty in generating higher pressure steam caused stignation in marine engineering practice; until the substitution of steel for iron in boller making, the advent of new types of furnaces, and improvements in the pressures as high as from 150 pounds to even 200 pounds to the square inch to be carried. The result has been that, for the two-cylinder compound engine, there have been substituted two types of engine, known respectively son engine. The names are maleading, as even the ordinary compound engine expands its steam more than

three or four times.

The growth of the science of marine engine design, which we have so briefly sketched out, may appear, to those who are not engineers, but little more than a record of increasing steam pressures. Undoubtedly a higher steam pressure has been the fundamental reason for these advances, but the carrying out of these successive changes in pressure has necessitated an entire reconstruction of marine engine practice; so that an engine working at 15 category as one working at 150 to 200 pounds pressure Tooth-wheel gearing, which was first used with screw propellers, has long ago disappeared, side levers and trunks are no longer introduced, and the surface condenser has become a necessity. In the old days, with jet con-densers, the boilers were fed entirely with salt water, now in the best marine practice the condensed steam is all returned to the boiler, excepting that which is unavoidably lost, and this quantity is made up by special distillers and condensers, the manufacture of which has introduced a new branch of marine engineering, as may be judged by several exhibits by different firms in the Exhibition. The practice of circulation of refrigerating water through the surface condenser by means of separate centrifugal pump-ing engines has also introduced a distinctive type of ing engines has also introduced a distinctive type of auxiliary marine engine, upon which several important firms have been chiefly employed. Indeed, the increase in auxiliary machinery has been as marked a feature in the recent progress of manne engineering as have been the changes in the main engines themselves. A battleship of the first class will carry between seventy and eighty separate engines, in addition to those used for driving the propellers. These include electric light engines, hydraulic machinery in connection with the working of heavy guns, steering engines, &c As an instance of what is gained by the use of auxiliary machinery, an instance given by Mr White may be quoted On one occasion it took 78 men 1½ minutes to put the helm of the Minotaur Steam gear was subsequently fitted, by the hard over aid of which two men were able to do the same thing in 16 seconds

We do not propose to gave a list of the various objects exhibited, to which we have referred in penning these remarks. The official catalogue performs that function far more completely than we could hope to do. The collection at Cheises is well selected and fairly complete, and the collection at Cheises is well selected and fairly complete, and the collection at Cheises is well selected and fairly complete, and the collection at Cheises is well selected and fairly complete, one of the collection at Cheises is well selected and fairly complete, which was a considered to the Director of Naval Construction. The cost of a too-gan line-of-battle ship at the beginning of the century was about £65,000 to £70,000, armainer The Cost of a too-gan line-of-battle ship at the beginning of the century was about £65,000 to £70,000, armainer principled checters of 1840 was about £10,000, and that of the 121-gan screw three-deckers of 1859 about £23,000, machinery included. The Warrior, completed in 1851, cost over £37,5000, and the Miniothur Class about £48,000. With the increase in see of the Directions@d, and the minothur class about £65,000 with the increase of the Direction of the Silver of Silver of the Silver o

The Mil and Trafator, complete with armament, would represent hitle less than a, million sterling each. The hydraulic gam combines are problem, machinery, and by draulic gam countings also greatly machinery, and private of Nelson's time. The sum paid for the armour alone on one of our latest battleships, such as the Neyal Soverage, would pay for the Natural History Museum at South Kennangton; whilst even a first class torpedo-boat costs as much to build and equip as a 40-gun firgate of Nelson's time.

A GEOLOGICAL EXCURSION IN AMERICA.

I BEG to call to your attention the following short account of a geological excursion planned for the benefit of foreign geologists who may attend the coming meeting of the International Geological Congress in this city in August next. It will afford an exceptionally favourable opportunity for European geologists to become personally familiar with the most important geological behomemen of the United States.

I venture, therefore, in their interest, to request that you publish some notice of it in your widely circulated periodical, with a request that those who desire to take periodical, with a request that those who desire to take not offer that arrangements may be thoroughly perfected beforehand. A single train will carry 75 to 100 persons comfortably I more poin, the party will be arranged in two trains. Arrangements will have to be made before the companion of the party, and you can therefore readily understand the importance of knowing as early as possible how many are to be accommodated.

S F EMMONS, Secretary Washington, D C. May 30.

For the close of the fifth session of the International Congress of Geologists, which is to be held at Washingcongress of vicinity states to be held a washing-ton, DC, from August 26 to September 2, a grand geo-logical excursion has been organized, which presents unusual attractions and facilities for the European geologists who attend the Congress, and who wish to see some of the geological wonders which have become familiar to them through the memoirs of American geologists. The excursionists will start from Washington, on September 3, on a special train of Pullman ves-tibuled cars, which will constitute a moving hotel, being provided with sleeping and toilet accommodations for both ladies and gentiemen, restaurant cars, smoking, reading, and bath rooms, and barber's shop, and so arranged that travellers can pass freely at all times from car to car through covered passages It will accompany car to car through covered passages It will accompany the party wherever the rails are laid in the regions visited, the hours being arranged so that all the most interesting portions of the route will be passed over in the daytime, and stops may be made wherever any object of special interest to the travellers presents itself. American geologists who have made special studies of the different regions visited will accompany the train, and explain their geological structure upon the ground. The main route laid out is over 6000 miles (nearly 10,000 kilometres) in length, and extends over 38° of longitude and 12° of latitude. It is planned to occupy 25 days, and the cost per person will be 265 dollars (1232 francs), which will cover all necessary expenses, of whatever kind, during the trip.

The following are the principal objects of geological interest which will be seen by those who make the

Going westward, the Appalachian Mountains are first crossed, and an opportunity will be had to see the closely appressed Paleozoic rocks which constitute their typical structure. The praine region of Indiana and Illinois, at the southern end of Lake Michigan, its ancient outlet

into the Mississippi River, will be seen on the second day, and the Kettle moraines of the ancient Glacial sheet will be visited under the guidance of Prof. Cham-berlin. On the third day the twin cities of Minneapolis and St. Paul, centres of the great wheat-growing region of the north-west, will be visited, and glacialists will have an opportunity to see one of the time gauges of the Glacial period, at the Falls of St. Anthony, on the Mississippi River

During the fourth day the Great Plains of Dakota will be crossed, and toward its close the characteristic Badland topography of the Upper Missouri region will be seen. On the morning of the fifth day the travellers will leave the train at the entrance to the Yellowstone Park, and during the following week will be transported by stages through the Park region, stopping at rustic hotels established near points of special interest. The various geyser basins, the hot lakes and mud volcanoes, the obsidian cliffs, the falls and canon of the Yellowstone River, the Yellowstone Lake, and other objects of interest. will be successively visited under the guidance of Messrs.

Arnold Hague and Jos P Iddings

On the twelfth day the railroad journey will be resumed, and, after crossing the crest of the Rocky Mountains in Montana, a stop of several hours will be made at the famous mining town of Butte, whose mines produced, during 1890, over 26 million dollars worth of

copper, silver, and gold.

The morning of the thirteenth day will find the travellers on the edge of the great lava plains of the Snake River Those especially interested in volcanic pheno-mena will have an opportunity here of making a side trip across these plains to Shoshone Falls, where the Snake across toese plains to Shosmone Fails, where the Shake river mikes a single leap of over 200 feet, and cuts a narrow gorge 600 feet deep in the andesitic and basaltic lavas. The main party meanwhile will proceed southward into Utah, viewing the desert mountain ranges, the shore-lines of ancient Lake Bonneville, and skirting the shores of its present relic, the Creat Salt Lake, will reach Salt Lake City, the Mormon capital, in the afternoon. A halt of three days will be made in Salt Lake City, which will give the travellers an opportunity of seeing the Mormons, the desert scenery around Salt Lake (with bath in the lake), and the magnificent Wahsatch Mountains The Pleistocene phenomena will be explained by Mr. G K. Gilbert, and the mountain structure and mining geology by Mr. S F Emmons.

On the sixteenth day the railroad journey will be con-tinued across the Wahsatch Mountains into the plateau region of the Colorado River, crossing that stream in the afternoon, and obtaining views of great monoclinal scarps, and groups of laccolitic mountains in the distonce

On the seventeenth day the Rocky Mountain region of Colorado will be entered, through its finest cashon gorges, affording wonderful geological sections. Halts of a few hours each will be made at Glenwood Springs and at the famous mining town of Leadville, which has produced over 150 million dollars worth of silver and lead.

On the cighteenth day the train will descend the great mountain valley of the Arkansas River, between mountain peaks over 14,000 feet high, and through cañon gorges 30:00 feet deep, debouching upon the plains through the Royal Gorge at Cañon City, where a remarkable geo-logical section in the "Hogback" ridges will be visited

logical section in the "Hogback" ridges will be visited a short stop will be made at Pueblo, a great centre of smelting works, and Manitou Springs, in a sheltered smelting works, and Manitou Springs, in a sheltered to the short should be seen at Manitou Strings, the vicinity of which abounds in objects of geological and mineralogical interests, and those who wish may make the ascent of Pike's Peak (14,200 feet) by rail. The twenticth day will be spent at Denvey, the cap tal

of Colorado, a beautiful city of 130,000 inhabitants,

having a view of the whole eastern front of the Rocky Mountains. For those who desire it, a further excursion of ten days or more will be organized under the guidance of J. W. Powell and C. E. Dutton, to the Great Cañons of the Colorado River in Arizona, which they have so fully described in their writings. More detailed visits to the mining districts of Colorado will be directed by S.F. Emmons for those who wish to remain over for that Those who remain over will receive tickets securing them passage to New York by regular trains

when they are ready to start The special train will leave Denver on the evening of September 21, crossing the Great Plains of Kansas and Nebraska and the Mississippi Valley, and reaching Chicago on the evening of the 23rd A day will be given to Chicago, and thence the train will skirt the Great Lakes, Michigan, Huron, and Erie, crossing a portion of Canada, and reaching Niagara Falls on the morning of September 25 Leaving there in the evening, the tra-vellets will descend the beautiful valley of the Hudson River early the following morning, and teach New York before noon of September 26

NOTES

THE Delegates of the University Press have informed Prof. Sylvester that they will be prepared to bear the expense of publishing in quarto a complete edition of his mathematical works We understand that a memorial recommending this course was addressed to the Delegates of the Press, numerously signed by leading mathematicians of the two English Universities, and by eminent members of the French Academy of Sciences

GEOLOGISTS on this side of the Atlantic will learn with deep scret that Captain Dutton, whose admirable memoirs in the Reports and Monographs of the U.S. Guological Survey are so widely known and valued, has been ordered to take up military duty in Texas-a wide pastoral region where his genius as a geological explorer will find no scope for exercise. As a member of the Corps of Engineers, he has of course always been liable to be taken away to mere routine service of this kind, for which any ordinary officer of his grade would be sufficient. But the authorities have hitherto appreciated his remarkable powers, and have allowed them free exercise, much to their own credit and greatly for the benefit of science. Whether a new martinet has resolved to apply the rigid rules of the service we do not know. But surely there ought to be public spirit enough in the United States to put such pressure on the Engineer Department as will make it reconsider its arrangements. It has only one Captain Dutton, and should be proud of him and make the most of him

THE Council of the Royal Meteorological Society has decided to arrange for a general dinner, open to all Fellows and their friends, to be held in commemoration of the catrance of the Society on its new premises. The dinner will take place at the Holborn Restaurant on Tuesday, July 7, at 6 30 p m

THE Committee appointed by the Hebdomadal Council, Oxford, to consider in what way the University could assist in the establishment of agricultural education, with a special view to the needs of the County Councils, have-now submitted their report. By agricultural education the Committee understand instruction in the sciences, or the branches of science, specially applicable to agriculture, employing the latter term with the larger meaning which must have been present to the mind of Dr. Slbthorp when he designated the professorship founded by him the professorship of "Rural Economy" Used in this sense agriculture becomes not merely the science of the cultivation of the soil, but includes the knowledge of its constitution and properties, of its vegetable products, and of the structure, habits, and uses of the domestic animals that are

reared apon it : so that the student has evidently much to gain by a knowledge of such subjects as botany, chemistry, animal physiology, and geology. Taking into account the requirements of the County Councils, the Committee think that the efforts of the University should in the first place be directed to the provision of an adequate supply of persons qualified to be lecturers or teachers; and those members who are most familiar with the wants of the counties lay stress upon the Importance of University teachers possessing credentials of practical acquaintance with the details of farming and farm-life, which has hitherto been only accidentally-if at all-acquired by such teachers. Other classes of persons whose circumstances the Committee think deserving of consideration are young men who go to Oxford intending to Take an ordinary degree, and then, either as landowners or the agents of landowners, to devote themselves to the pursuit and improvement of agriculture; and young men who might go to Oxford with a view to attending such courses of instruction as would be useful to them in agriculture, but without the intention of taking a degree. Dealing with the means already at the command of the University for providing agricultural education, the Committee point out that the professors to whose services resort would most naturally be had are the following the Sibthorpian Professor of Rural Economy, the Sherardian Professor of Botany, the Waynflete Professor of Chemistry, the Waynflete Professor of Physiology, and the Professor of Experimental Philosophy (Physics) In addition to these University Professors, there are the Lee's Readers in Chemistry and Physics at Christ Church, and the Millard Lecturer in Physics at Trinity College, whose courses would probably be open to agricultural students. The Committee sketch the proper course of study for each class of students, and express the opinion that for the organization and supervision of the studies pertaining to agricultural education some further provision is needed than at present exists. In the Sibihorpian Professorship of Rural Economy, which is now vicant, they recognize a foundation capable of being rendered the centre of agricultural education within the University, and they strongly recommend that the duties and emoluments of the chair should be revised.

THE annual dinner of the Royal Hortcollural Scotely was a held on Tuesday evening at the Hivel Mitropole The chair and was laken by Sir Trevor Lawrence, the President The toast of the evening. "The Royal Hortcultural Society," was proposed by Sir James Paget, who spole of the work in which the Society was engaged as one that minutezed to the happiness so and welfare of the whole nation. The President responded, the The Society in own as most prosperous condition, and is to be congratulated on the progress it has made under Sir Trevor Lawrence's leafership.

WE print elsewhere a report of the lecture delivered by Lord Rayleigh at the Royal Institution last week in connection with the Faraday Centenary In commemoration of this anniversary the Royal Institution elected as honorary members a number of foreign men of science, several of whom came to London to be presented with the diploma of membership by the Prince of Wales. As the distinction between the Royal Institution and the Royal Society is not always so well understood in foreign countries as it is in England, the Royal Institution can hardly, perhaps, be congratulated on this "new departure." The follow ing is the list of those on whom the honour was conferred -Edmond Becquerel, Marcellin Berthelot, Alfred Cornu, E Mascart, Louis Pasteur, Paris, R. W. Bunsen, Heidelberg; H. L. F von Helmholtz, A. W. von Hofmann, Rudolph Virchow, Berlin ; J. P Cooke, Cambridge, U.S., J Dwight Mbbs, Newhaven, U.S.; Simon Newcomb, Dana, J. Willard Washington, U.S., Stanislas Cannizzaro, Pietro Tacchini, Rome ; Julius Thomsen, Copenhagen ; T. R. Thalen, Upsala ; Demetri Mendeleef, St. Petersburg ; J. C. G. de Marienac.

Geneva; J. D. van der Waals, Amsterdam; J. Servais Stas, Brussels.

A COMMISSION has been appointed for the reorganization of the Paris Museum of Natural History, and held its first meeting last week under the presidency of the Minuter of Public Instruction The members are MM Berthelot, Bardoux, Burdeau, Charles Dupoy, Darboux, Frémy, Chauveau, Milne-Edwards, and Lazrd

A conversations will be given by the President of the Institution of Electrical Engineers and Mrs Crookes in the galleries of the Royal Institute of Painters in Water Colours on Monday evening, July 6.

On Monday evening, in the House of Commons, Sir H. Roscoe asked the President of the Board of Trade whether he had decided to grant the application of the Committee of the National Institute of Preventive Medicine to become incorporated under the Companies Act, with the omission of the word "limited" in view of the amended proposals which had been placed before him Sir M Hicks-Beach replied as follows .-"The amendment of the proposed memorandum of association referred to by the hon member (by which it is made clear that the grant of the licence now asked for would not in any way maply approval by the Board of Trade of experiments upon living animals, or of any application to the Home Secretary for a licence for that purpose) is, no cloubt, an important change in the proposals of the Institute, and will probably meet the objection stated to the deputation which lately waited upon me. There are, however, one or two other points requiring consideration, but I hope shortly to be able to arrive at a decision on the subject "

Sis Pres-Coll Gardiner Hewert, F.R. S., died on Friday inght last at his residence, Chesinut Lodge, Horsham, Susser. IIc was born in 1812, and in 1836 was admitted a member of the Royal College of Surgeons, of which he was made President in 1876, in succession to bur James Paget.

Witt the approval of the Preudent, the Prance of Wales, the Council of the Society of Arts have awarded the Albert Medial to Sir Frederick Abels, K C B, "in recognition of the manner in which he has promoted as veral important classes of the arts and manafeature, by the application of chemical science, and especially by his researches in the manufacture of iron and of steel, and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as chemist to the War Department."

THI. Report of the Savilian Professor of Astronomy has been presented to the Board of Visitors of the University Observatory, and we learn from it that the photographic telescope, prepared for taking part in the International Chart of the Heavens, is at length complete. The guiding telescope also is provided with a micrometer sufficient to permit the observation ot stars at a considerable distance from the centre of the plate. and the camera end of the telescope is fitted with the apparatus devised by the Astronomer-Royal, and executed by Sir Howard Grubb The Oxford University Observatory is also provided with two researce, supplied through Dr. Vozel, of the Potsdam Observatory, and has very recently added to its equipment a measuring machine of great delicacy for the discussion of the plates taken in connection with the international scheme. Altogether the equipment of the Oxford University Observatory appears to be in a very forward state of preparedness, and Prof. Pritchard congratulates himself and the University that this equipment has entailed no unusual appeal to funds, on which there are so many claims, but has been supplied by the bounty of the late Dr. De La Rue, supplemented by strict economy in the management of the Observatory in former years. The astronomical work of the past year has been mainly confined to the discussion of the parallax of stars of the second magnitude,

and this work is now on the brink of accompletament. Series complete determinations, including that of B Aurigee, have been made in the year, and but it to ther stars, the measures of which are complete, await discussion. Prof. Pritchard concludes his Aegorit as usual, by acknowledging the aid he has received from his two assistants and we are glad to see speaks hopefully of his terostation to complete health.

This President of the French Republic inspected the meteorological instruments at the summit of the Eiffel Tower on June 13, and afterwards visited the Central Meteorological Office, where he witnessed M. Weyer's experiments on the formation of tornadoes, and also inspected the instruments which there reguler the indications of the meteorological phenomena at the top of the Eiffel Tower.

THE French Minister of Public Instruction has appointed Dr. Henry de Varigny, assistant in the Museum of Natural History, to report on the University Extension movement, and has commissioned him to study the question in Edinburgh, London, and Oxford.

THE proposed law on Universities is existing a good deal of discussion in Frame Many local jealouses have been aroused in connection with the question. Every town this bosts to possistion of a tenth rate medical school, or of an inadequate scientific faculty, whelse to have a University, and its political calmir. On the other band, do what they can to peen its claim. On the other band, and the substitution willingly establish five or at most ax large Universities, desire fig passible, to do away with mail and subsets institutions.

A SCIENTIFIC expedition which has been organized in Maine is about to spend some time in Labrador. The principal object of the party will be to collect ethnological specimens. They will take with them a phonograph, with which they hope to obtain some materials for the study of the language and songs of the Eskimo.

In drawing up sciences for the appropriation of the funds of placed at their disposal under the Local Taxation Act, 1800, for the promotion of technical instruction, the County Councils the promotion of technical instruction, the County Councils in the claims of girl's cineation. With a view of adding County Councils in this department of their work, the Committee of the National Association for the her work, the Committee of the National Association for the Committee of the National Association for the Promotion of Technical and Secondary Education has submitted for girls, and included within the stope of the Technical Instruction Acts it is suggested that in each county a committee of ladies should be appointed to devise and carry out a scheme for the technical education of girl.

THE Suster Daily News of June 18 records the birth of a sea iton at the Brighton Aquarium.

On June 18, sixty distinct shocks of earthquake occurred at Serajgunge and Domar, in the Bengal Preudency. Many buildngs were slightly damaged. At Serajgunge continuous earthquake shocks had been felt from noon on the preceding day.

ACCORDING to a telegram from Rome, dated June 22, a strong shock of earthquake was felt that morning at Avighano and at Aquila.

IN his report on the Royal Boiann Gardens, Ceylon, for 1890. F. Timen refers to the kinds of cases on equivation there. There is no reason to support, he says, that they have useler cultivation more than one spectre of Theodoman, but every probability that all the varieties trace their origin to a common wild parsent. It would be interesting to know which for the two fairly well-marked races recognized in Ceylon is the nearest distribution of the control of the two fairly well-marked races recognized in Ceylon is the nearest distribution. The control of t

was erer really a native plant there. It was, however, the sort at one time esclosurely grown in that island, where, having died out, step lace was supplied by the "foreign" sort, no doubt bottlande from the maninad. As seen in Ceylon, the "Croslot" (called also there "Carnoa" and "Old Ceylon Red Casco") presents very little awaterly, but the "Pornstero" shows a redoubt crossing goes on freely in plantations even between the two mans races, and it is well known in Ceylon that seed from a single tree gives a very varied progeny, but a cursous remark was recently made to Dr. Timen by a large grower, who has great opportunities for observation, that the "Pornstero" varieties, which the chiefly enhances, appar to be gradually caractes, which the chiefly enhances, appar to be gradually Ceylon Eck." the seeds loang that dark colore on section, and becomes place or nearly white.

In Himmel and Erde for June, Prof G Hellmann, of Berlin, berns a series of articles entitled "Meteorologische Volksbucher," being an inquiry into popular and typical ineteorological works from the earliest times, and into the nature of their contents. The works to be discussed are more particularly those of Germany, although foreign literature will also find subudiary consideration. Two works are referred to in the present article -(1) "The Book of Nature," by Konrad von Megenberg, which is the oldest natural history in the German language, and was written about the year 1350-nearly a century before the invention of printing. It was first printed in 1475, and went through many su'sequent editions Much attention and original thought was given to meteorological subjects, and the author divided the wind rose into 12 points but the work is to some extent based upon a still unpublished Latin manuscript by Thomas Cantimpiatensis, "Liber de natura rerum," which was written before the middle of the 13th century (2) "Elucidarius" The author of this work is not known with certainty, but is supposed to be Jakob kohel This remarkable work was first published in German, in the year 1470, and was much sought for in 1910st European countries in the 15th and 16th centuries. It deals with a variety of subjects, including meteorology and geography, and many editions were published in various countries Dr Hellmann gives copious extracts from the works, and historical research being a subject in which he carries great authority, his treatment of it will be found both interesting and instructive

MISSES. VIEWEG AND SON, of Brunswick, intend publishing a German translation of Mr Denning's new book, "Telescopic Work for Starlight Evenings"

A Work entitled "Synopus der Hohene Mathematik", by J. G. Hagen, Director die Georgiewom College Observatory, Washington, D.C., is to be published by Felix L. Dames, Berlin The work is the result of labour carried on continously during twenty years, and is intended to present a general view of the higher mathematics. It will consist of four volumes, the first of which will be massed easily in August

A VALUABLE paper on gum-tree, by Mr. D. McAlpine and Mr. J. R. Rendry, has been reprinted from the Transactions of the Royal Society of Victions for 1890. There are several ultistrative plates, the drawings being puniopally reproductions of photographs taken by Mr. Rendry. These drawings show that the transverse section of the leaf-stalk of a basalypt may reveal a pattern useful in the determination of species.

MESSES. GEORGY PHILLIP AND SON have issued the first number of the Blue Peter, a monthly sailing list and review. It is intended that the new journal shall provide ample information for persuan who are about to set out by any one of the principal ocean routes. There will also be articles which may serve to remind ships' officers that "there is substantial [profit to be derived from a scientific training). THE third volume of the *Photographic Recorder* is completed by the June number. The volume is admirably illustrated, and contains a valuable record of all that has been done in connection with photography during the past year.

MESSES W. F. BROWN AND CO., Montreal, are printing for the Government of Canada "Contributions to Canadam Palaeontology," by J. F. Whiteseve, Palaeontology and ACologist to the Canadam Survey. Part iii. of vol 1. has just been tssued. It deals with the fossils of the Devonian rocks of the Mackenine Rwer Datin.

A NOTE by M. Moissan upon the action of fluorine upon phosphorus trifluoride is communicated to the current number of the Bulletin de la Société Chimioue. A short time ago M Moissan described a mode of preparing the gaseous trifluoride of phosphorus The method consisted in gradually adding phosphorus tribromide to warm zinc fluoride, washing the gas first through water, in which it is sparingly soluble, and afterwards drying by means of pumice moistened with sulphuric acid and collecting over mercury. In order to study the action of free fluoring gas upon phosphorus trifluoride as thus prepared, a special piece of apparatus was devised, constructed entirely of platinum and fluor-spar. It consisted of a plannum tube fifteen centimetres long, closed at each end by transparent plates of fluor-spar, through which the phenomena attending the reaction could be observed. The platinum tube was fitted with three side tubes, two of which were placed opposite each other about the centre of the tube, and served for the admission of the fluorine and pho-phorus trifluoride respectively. the third or exit tube was of somewhat wider diameter than the entrance tubes, and was bent so as to serve as a delivery tube over a mercury trough. The whole apparatus was first filled with phosphorus trifluoride, and then the fluorine entrance tube was connected with M Moissan's now well-known apparatus for the preparation of fluorine As soon as the fluorine came in contact with the phosphorus trifluoride a vellow flame was produced and intense action occurred, with the production of phosphorus pentafluoride. The flame appears to be a comparatively low temperature one. On collecting the gaseous product over mercury, it was found to consist very largely of phosphorus pantafluoride, readily capable of absorption by water, and a small proportion of unaltered trifluoride which could be absorbed by potasb. This reaction of fluorine with trifluoride of phosphorus is thus analogous to the conversion of phosphorus triebloride into pentachloride by the action of gaseous chlorine. An interesting reaction has also been observed by M. Moissan to occur between spongy platinum and these gaseous fluorides of phosphorus. When pentafluoride of phosphorus was passed over spongy platinum gently heated in a platinum tube, a partial decomposition was found to occur, and the issuing gas was admixed with trifluoride, and also with free fluorine. The existence of the latter in the free state was abundantly shown by its action upon crystallized silicon When, however, the temperature of the tube was raised to dull redness, a volatile compound, containing platinum, phosphorus, and fluorine, was obtained, which was carned forward by the gaseous current and deposited in crystals in the cooler portion of the tube. When this crystalline substance is heated. it melts to a viscous liquid, which decomposes at a bright red heat. Analyses show that it is a fluophosphide of platinum, probably of the composition 2PF, PtF, analogous to one of the similar chlorine compounds discovered by Schutzenberger, 2PClg. PtCl. M. Moissan expresses the hope that by employing some such dissociating compound as this a purely chemical isolation of fluorine may some day be achieved.

THE additions to the Zoological Society's Gardens during the past week include three Stoats (Mustila erannea), European, presented by Mr. J. S. B. Borough; an Ocelot (Fels pardate 8) from South America, a Red-tailed Buzzard (Butto borcatts), a

Laughing Gull (Larus atricilla) from North America, presented by Sir Henry Blake, K.C.M.G.; a Tawny Eagle (Aquila navioides) from Africa, presented by Mr. K. G. Hay; a Blue-fronted Amazon (Charactic astron) from South America. presented by Mrs. A. G. Mussey; a Grev-breasted Parrakeet (Bollorhynchus monachus) from Monte Video, presented by Mr. J. R. George , four Common Qualls (Coturnix communit), British, presented by Mr J C. Gie; two Chinese Geese (Anser cygnoides) from China, presented by Captain Creaghe; an Egyptian Gazelle (Gazella dorcas) from Egypt, two Abyssinian Guinea Fowls (Numida ptilorhymha) from Abyssinla, two Blossom-headed Parrakeets (Palcornis evanocephalus) from India, a Meyer's Parrot (Pascephalus meyers) from East Africa, three Til etan Crossoptilons (Crossoptilon tibetanum) from Tibet, a Temminck's Tragopan (Certornis temmincki &) from China, deposited; a Vinaceous Amazon (Chrysotis vinacea), from Brezil, nurchased : two Heloderms (H. la ferma sustectum) from Arizona, U.S.A., received in exchange; a Burrhel Wild Sheep (Ovis burrhel), two Mule Deer (Carracus macrotis & 8), & Bennett's Wallaby (Halmaturus bennetts &), two Impeyan Pheasants (Lophophorus impeyanus), bred in the Gardens

OUR ASTRONOMICAL COLUMN.

TRANSIT OF MERCHY—The Government Astronomer as Sydney (Mr. C. Todd, C. M. G.) writes as follow; regarding the transit of Mercury.—Good observations of the transit of Mercury were secured as the Observation, on Sinday, the study is increased as the Contraction, on Sinday, the study is largered the conditions were extremely favourable, the study is many larger of the study of the study of the study is many well and sharply defined, but at the egrees the sun's inab was bosing and the planet was somewhat woodly, rendering it difficult to fix the exact time of internal contact. I observed with the S-inch equational refractor, assisted by Mr. Cooke; and Mr. Sello observed with as B finet freederor.

Observer—C Todd, Power 125.

values of e and the mean intensities of the lines at the two stations. The scale of intensity is such that the C line = 10, and the line at 651'55 is unity

SIMILARITY OF THE ORDITE OF CRETAIN AS EROIDS—In the Publications of the Astronomical Society of the Pairfic, No. 15, 1851, Prof. Daniel Kirkwood gives a list of twenty-four asteroids arranged in ten groups, according to the similarity of their orbits. The following are the groups—

Jupiter is held responsible for the perturbations necessary for the development of these groups of asteroid orbits from the primitive solar nebula.

ASTRONOMICAL AND PINNINA SOCIETY OF TOWNSTOthe first number of the Transactions of this Society (1850-01), with which is also included the first Annual Report, has recently been asseed. It contains abstracts of several intercenting pagers of Saturn's rings, by Dr. Uormion, two by Mr. Shearman on coronal photography, and two by Mr. A bullet on the spectracopic. A drawing of a van spot observed on November that the contains of the substraction of the contains of the contains the frontainpiece of the number.

A New ASTEROID (11) -On June 11 M. Charlots discovered the 311th asteroid. Its magnitude was 13

THE ROYAL SOCIETY CONVERSAZIONE

THE Ladies' Son's of the Royal Society was held on the 17th instant, and was very numerously attended. The following were among the chief objects exhibited.

Finger-prints as a mean- of identification, exhibited by Mr.

Finger-prints as a mean of identification, exhibited by MT Francis Galion, F. K. 5. (1) Specimens showing the nature and character of the patierts that are formed by the papillary ridges on the falls of the finges, as well as on the rest of the persistence of the patierts in their essential details, most of the persistence of the patierns in their essential details, most of fingers infascy to age. (3) Method of indexing a collection of fingers prints so that a determination may be quickly arrived at, whether the duplicate of a given specimen so contained in it or not. (4)

prints so that a determination may be quickly arrived a, whether the duplicate of a given specime in contained in it on not (4). Process of making finger-prints, exhibited in operation. Registration of colours in numbers, and apparatus to show the Registration of colours in colours, and apparatus to show the captain colours, exhibited by Captain charge, of B. Every of the different colours, exhibited by Captain charge, of B. Every of the colours of the registration consists in referring any mixed colours to a single wave-length, and a percentage of white light. With the apparatus to show the greater sensitiveness to the eye of different colours, a comparison is made by placing two colours aide by the distribution of the colours of

An optical liliuson, exhibited by Prof. Silvanas P. Thompson, F.R.S. On two rotating dails, A and B, are spin patterns in black and white, which seem to move radulty inwards and out-wards respectively. Let the observer gase facetly of a bout one work of the contract of the part of

Mr. Walter Gardiner, F. R. S., gave demonstrations of certain important phenomena associated with the absorption and the flow of the water taken up by plants—10! Root pressure Water present in the soil, and containing minute traces of until the salt, as absorbed by the root-hairs an powerfully and in such quantiles as to set up a considerable pressure in the interior of the plant. This "root pressure" may be demonstrated by attaching to the cut end of a stem a manometer containing mercury, or some coloured fluid. Here a solution of ingrounce in water is employed. (2) The transpiration current.

Among the more important factors which determine the flow and ascent of water from the root, upward, is the sucking force and used by the modeled everpown or transprintion of water modeled the modeled everpown or transprintion of water than the second of the water escapes as wapour, and the salt are retained for food. In this experiment the existence of a "transpriation current" is shown by allowing a cut branch to suck up milk, when the movement of the fat globuler suggesters the flow of the liquid. (3) The amount of water absorbed by the root. This may be estimated by unplue measurement, employing some such form of

estimated by simple measurement, employing some such form of apparatus as that exhibited.

Engravings to "Travels among the Great Andes of the Equator," exhibited by Mr Edward Whymper. These illustrations are elections from Mr. Edward Whymper's forthcoming work upon the Great Andes of the Equator (in which he gives accounts of the first arcents of Chimborazo, Cayambe, Antisansi, &c., &c), and includes views on and about the equator at great elevations, incidents of travel, numerous examples of the new elevations, incidents of travel, numerous examples of the new generas and species obtained on the journey; a facismite reproduc-tion of the map of Don Pedro Maldonado (upon which existing maps of Ecuador are based), and the original route survey, and map of Climborazo, made by the author. The work, with 200 cultustrations and four maps, will be published in the present

illustrations and four maps, will be published in the present year by Mr John Murray
Mr W Bateson exhibited (1) models of double super numerary legs and antenne in heetle-, (2) mechanical model showing the usual symmetry of double supernumerary appendages in beetles. Supernumerary appendages in beetles nearly always spring as branches from a normal appendage, and are generally double, being made up of two limbs more or less compounded together. The two extra limbs are always a comgenerally double, oring made up of two imms more or ex-compounded together. The two extra limbs are always a com-fementary fears, one being structurally a right limb, while the other is left. Commonly the symmetry of the parts is arranged as follows —(a) The two extra limbs and the normal one stand in one plane, one of the extra limbs being nearer to the normal limb and one remoter from it. (b) The nearer is in structure and position an image of the normal limb in a mirror stucture and position an image of the normal lumb in a mirror at right angles to the plane in which the three limbs stand; and the tender is an image of the nearer in another mirror beyond their exercit positions may be represented by the mechanical moiel exhibited, in which the extra legar, evolving round the mormal leg, take attudes proper to the positions which they occupy relaively to the normal leg, take normal leg and norma

and the progressive and retrogressive evolution, of art and ornament in British New Guinea. The exhibit is designed to ornament in British New Gunea. The exhibit is designed to show that savage art can be studed as a branch of biology, and that it is only when so treated that it yields its most valuable limited geographical range, and those which have a wide dis-tribution can, in the misjoilty of cases, be proved to be hom-plastic and not homogenetic. The revolution of a particular pattern must be sought in the district in which it occurs, and its developmental thatory can only be saiely attempted when a comparison is made of numerous objects from the same locality The foregoing propositions are illustrated by means of specimens, rubbings, photographs, and sketches of decorated objects from British New Guinea

SCIENTIFIC SERIALS.

American Journal of Science, June —The study of the earth's figure by means of the pendalum, by E. D. Preston. The author first deals with the history of the subject, then states the quantities involved, and supports the method of andy in which the figure of the earth is considered separately from its size as determined by measurement of arcs of meridian. The general results of pendulum work are discussed, and the effect of contrential attraction and variations in latitude referred to The best methods of determining the duration of a pendulum oscillabest methods of determining the duration of a pendulum oscilla-tion at a given temperature and pressure are also considered —On the pote-glacial history of the Hudson River valley, by Prederick J H. Mervill The result of the scino of waves-resulted to the present of the scino of waves-ters and elevation, a sense of terraces will be formed, if the land is alonly rating or subsiding with respect to sea-level, an inclined plane of ensoin may be produced. A groung from this and other facts, the author states provisionally that, after the retreat of the continental glacer from the Hudson River valley, the land stood commentar gater from the Indion New Aucy, the land stood for a long time at a lower level than at present. A gradual elevation and extensive erosion of the Champlain estuary deposits in the river valley then occurred, and was followed by a depression amounting to about 100 feet at New York, and which is son amounting to about 100 feet at New York, and which is apparently continuing at the pre-ent day—On alunte and diaspore from the Routa fills. Colorado, by Mhitman Cross—Diaspore crystals, by W. II. Melville—Combustion of gajets under pressure, by R. W. Wood. Anyone who has watched a burning jet of ether yawoow will have noticed that, as the pressure increases, the flame gradually retreats from the orifice and eventually goes out if the pressure is carried beyond a certain point. The author has investigated these phenomena, certain point 16. author has investigated these phenomena, sing various gases. A burning jet of co. align was estinguished when the pressure was equal to 23 centinetres of mercury—that is, when the velocity of the issuing gas exceeded the speed of combustion for the mixture of gas and air.—Allotropic silver part iii, blue silver, soluble and insoluble forms, by M Carey Fart in, blue silver, soluble and insoluble forms, by M. Carey Lea. From the results given in this and preceding papers, the author is led to believe that allotropic and even soluble silver may be formed in numerous ways. The reducing agents may be either a ferrous or a stannous salt, or any one of a variety of organic substances of very different constitutions. From the solubility and activity of this substance, and the parallelism which many of its reactions show to those of silver in combination, it appears probable that silver in solution, like silver in combination, exists in the atomic form -Note on the submarin combination, exists in the atomic form —Note on the automatine channel of the Hudson River, and other evidences of post-glacual subsidence of the middle Atlantic coast region, by A. SOCIETIES AND ACADEMIES. LONDON.

Royal Society, June 18 — "Results of Hemisection of the Spinal Cord in Monkeys." By Frederick W. Mott, M.D., B.S., M.R.C.P. Communicated by Prof. Schafer, F.R.S.

B.S., M. R. C.P. Communicated by Prof Schaler, F. K. S. While engaged in studying experimentally the connections of the cells of Clarke's column with the ascending mets of the cells of Clarke's column with the ascending mets of the themsection in the lower dorsal region the sensory disturbances produced in no way corresponded with those already obtained by eminent observers.

by ennent observer.

I was therefore led to continue my experiments, and, by
the kind permission of Prof. Schafter, I carried them out in the
same and the schafter of the schafter of the schafter of the
same stone due to him for much valuable advoce and samitance.
The subject is one of great importance from a scentific, as
well as forth a clinical, point of verw. None years ago, a case
occurred in my practice which tended to skake my faith in the
shapilate train by the doctrum of complete and immediate decou-

vation of sensory impulses in the spinal cord, as taught by Brown-Séquard. The experiments which I have performed exhibit the following

principal points of interest :-
(1) Return of associated movements after complete destruction

of the crossed pyramidal tract below the lesion

100

of the crossed pyramidal tract below the festion (2) That all sensory impulses do not decessate in the cord—in fact, they appear to show that certain sensory impulses, e.g. touch, the muscular sense, and localization in space, pass findly up the same side, painful impression up both aides. A peculiar condition known as "allochia" occurs after hemisection.

condition known as "automiria" occurs after neinsection.

(3) The vaso motor disturbances are on the same ride as the lesion, and consist of vaso-dilation, swelling of the foot, and redness with rise of temperature of the skin of the foot (as compared with the opposite side), and fall of temperature in the popliteal space on the side of the lesson, due, no doubt, to paralysis of the muscles.

The degenerations above and below the lesion are limited (4) The degenerations above and below the lesion are limited to the same side when the injury is perfectly unilateral. There are certain facts connected with the degenerations which serve to

show the origin and course of certain long and short tract fibres

(5) Stimulation of the cortex cerebri on both sides some weeks or months after the hemisection had been performed gave, as a rule, results which showed that the block in the spinal cord produced by the hemisection still existed, although there had

been a very complete return of associated movements.

(6) In one case ablation of the leg area on the same side as the lesion in the spinal cord was performed many months after-

Chemical Society, May 2t -Prof A. Crum Brown, F R S . President, in the chsir.—The following papers were read:— Bromo derivatives of betanaphthol, by H. E Armstrong and E C Rossiter. The authors have completed the study of the compounds formed on brominating betanaphthol, to which they have referred in two previous notices (Chem. Soc Proceedings, t889, p 7t, 1890, p 32). In the present paper they give directions for preparing tri- and tetra bromobetanaphthol, and summarise the properties of the bromobetanaphthol, and product of the action of bromine in excess on betanaphthol, has been carefully examined without any substance having been discovered which affords 1 · 2 · 3-bromophthalic acid on oxidation, the discrepancy between the author' observations and the earlier experiments of Smith and Meldols, therefore, yet remains to be discovered — The action of antire acid on mobile. experiments of Smith and Meddos, therefore, yet remains to be discovered —The action of intrin ead on anyhthol derivative as indicative of the manner in which intration is effected in the case of bensenoid compounds generally; the formation of nitro-keto-compounds, by II, E. Armistrong and E. C. Rossitter. The chiloro- and brome-derivatives of betanaphthol when warmed The cnirco- and bromo-certificate of cetan pathol when warmed with nitre acid are converted into derivatives of betanaphtho-quamon; but the formation of these compounds is preceded by that of an unstable intermediate compound. These intermediate compounds, when carefully bested, are converted into derivatives of hetanaphthaquimone. Thus, when nitric acid is added to dibromobetanaphthol, suspended in acetic acid, a clear solution is obtained which, after a short time, deposits a crystalline. substance; if quickly evaporated by filtration, this product is almost colourless, but it decomposes when kept, becoming yellow. This compound, when treated with alkali, yields bromonitro naphthol. Bromobetanaphthol, in like manner, yields a nitro-betanaphthol, and the tri- and tetra-bromo derivatives yield di-and tri-bromonitrobetanaphthol. The authors are of opinion that the intermediate compounds in question are nitro-bromo-keto derivatives, and that their formstion affords evidence that the elements of nitric acid first become added to the bromonaphthol, thus .-

The theory that the formation of such addition-compounds grecodes that of intro-compounds generally, appears to afford a satisfactory explanation of a number of well known fasts which hitherto have remained unexplained. The non-production of the compounds of the compound of the formation compounds of the department of the three compounds of the formation of intro derawitives of phrashes on intrasting hydrocarbons, for if the addition compound lose H.NO₆ instead of H OII a phead would result, thur—

An agent which would tend to withdraw water from the addition compound would increase the production of nitro-compound tion composind would inferease the production of mirro-compound and diminish that of phenol, and it is known that when a mature of nittee and subplurie acids is used, there is less of the phenol derivative produced than when nitric acid alone is employed. A composnd like the addition-compound of benzene, represented above, would obviously be unstable, and prone to undergo on the properties of the properti oxidation, hence the explanation of the large amount of nitrous fume produced on nitrating benzene. The non-production of resinous matters when sulpho-acids are treated with nitric acid resnows matters when supposed are dealed with finite con-to form the corresponding nitro-compound by displacement of the SO_1H group by NO_2 is also elucidated by the authors' theory, the addition-compound formed in such a case would theory, the addition-compound formed in such a case would very readily break up into sulphuric acid and the nitro-derivative —A new method of preparing nitro derivatives, and the tive —A new method of preparing nitio derivatives, and the use of introgen choldle as a nitraing agent, by H. E. Armuse of introgen include as a nitraing agent, by H. E. Armcompounds formed by the addition of the elements of nitric acid
on the bromo derivatives of betanaphilo) upich nitro-derivatives
of the naphthol on treatment with alkali, a bromine atom becoming displaced by NO₂. On treating the addition-compound with sulphurous acid, a practically theoretical yield of the nitro-naphthol is obtained: this method appears to be of general application. The authors have been naturally led to study the action of nitrogen-doxide, NO₂, on un-attracted compounds of various kinds, in the hope of obtaining addition-compounds which by loss of HNO₂ would pass over into intro-derivatives of the substances treated. They find that such addition-compounds are obtained, and on treatment with alkali and reducing pounds are dottained, and on treatment with a listal and reducing-genety yield nitro-compounds. Thus bennaphind) yield 75 per cent. of its weight of intro-betanaphilid, alphanaphthol be-haves similarly. Phenol yields orthe- and para-nitrophenol. The authors propose to study the action of nitros acid and nitrogen dioxide on unsaturated compounds generally from the point of view indicated in this and the previous note.— Narification, by R. Warngton The first section of the paper describes early experiments, showing the existence of an a producing only nitrites, and the means of separating it from pronoung only nitries, and the means of separating it from soil Successive cultivation in ammonizaci volutions made per-manently alkaline with disodium carbonate was found to be a certain method of obtaining a purely nitrous signit. Pasture soil yleided the nitrous agent more readily than arable soil. The introus organism was solated by the dilution method. Cultiva-nitrous organism was solated by the dilution method. Cultivations were made in an ammonium chloride solution with calcium earbonate The nitrous organism oxidizes ammonia to nitrous acid, and has no effect on nitrites. It produces nitrous acid in solutions of saparagliae, milk, uriae, and ures. Grown in broth contaming calcium nitrate, it does not reduce the mirate to nitrate. It requires no organe matter for its naturiton, and its nitrate, it requires no organe matter for its naturiton, and its nitrate in the presence of either aclicium or sodium and carbonate distinctly favours mirification; neutral sodium carbonates greatly hadren mirification. The nitrout organism occurs as nearly meaning the paper deals with the nitrit organism. The results show that the nitrit organism develops freely in anonymic carbonates are present. Monocodium carbonate, 1-4 grams per litre, exerted a very favourable influence; 6 grams per litre, a returning misense. Dissolution achionate greatly hinders the action. The nitric organism produces nearber altered to mise of the content of the parties or nitrates for mirrate in minuscial colution. The the absence of solutions of asparagine, milk, urine, and ures. Grown in broth

ammonia, it energetically converts nitrites into nitrates, the presence of ammonia is apparently a great hindrance to its action. An attempt to isolate the organism failed. The nitrification performed by soil thus appears to be the work of two
organisms, one of which oxidizes ammonia to nitrite, while the
other oxidizes mirrite to nitrate.

conter consuces turne to nurse. — Sir Archibad Cerkie, F. R. S. Descolegical Society, June ere a bommentement of the general business, Frof. Blake rose on behalf of those present at the meeting to congruntate the President on the honour that it had pleased Her Mujesty to confer upon hum. No was deserved, and the closelgical Society would doubtless teel also the honour conferred on their scene is the person of their President and the head of the Cerboglical Survey of the United Freedens and the head of the Geological Survey of the United Kingdom.—The following communications were read—Note on some recent accessions, in the Wellingson College dutter? —Note on deposits on the south coast of England, by Mr. Affred Bell Communicated by Mr. R. Alberdage, F. R.S. The author's object in this paper is to trace the successive stages in the development of the present coast of the north sade of the English Channel, and to sceration the sources of the diversified of the present coast of the north sade of the stages of the control of the present coast of the north sade of the control of the present coast of the north sade of the control of the present coast of the north sade of the control of the present coast of the north sade of the control of the present coast of the north sade of the control of the present coast of the north sade of the control of the present coast of the north sade of the The first traces of marine action on the south coast in post-Textary time, are found on the foreshore in Biack-leaham Bay. The subtor's reading of the section is somewhat different from that of the late Nr. Godwin-Austen, and he divides the marine series unto (1) an estuarine clay with Mollusca common to estuarine flats, (2) a compare hard mod, and (3) a bed of change from estuarine to uterp-water conditions. A full his of this Selesy fossile is given, including, amongst other animals, pawards of 200 Mollusca. Of 35 process of Mollusca sont now living in Britain, the majority exist in Lisatianian, Medisterrates, or Aircas waters, furthermore, nearly 45 per cent. of the Mollusca are common to the older Crago of the eastern consurance and continuous control of the Changel Bulberton of the post-Tertiary times, are found on the foreshore in Bracklesham adleate the further opening of the Channel subsequent to the formation of the Severn Straits, and believes that this fauta tormation of the Severn Straits, and believes that this fauta represents the deposits wanting between the Selsey mud-deposits and the erratic blocks which, according to him, overlie the mud, these Porlland shells indicate an intermediate temperature, "rather southern than northern," according to Dr Gwyn ure, ""suber southern than northern," according to Dr. Gwyn pelfersy. In conduction, datails concerning still never beds are given, and into of fessils found theren, and the author observed from the conduction of the conduction of the conduction of the finally opened up, beyond the suggestion of Mr. todown-hasten that, if the Sangatie beds and the Coombe Rock are of the same period, it usus have taken place after their formation After the reading of this paper some remarks were made by Mr. Etherdeg, Mr. C. Real; Port Hull, and the author.

EDINBURGH Royal Society, June 1—Prof Chrystal, Vice-President, in the chair—Prof. Tait communicated a paper, by Prof Piazzi Smyth, on two series of enlarged photographs, one in the visible, the other in the invisible, of the visit of the solar vasible, the other in the invisible, of the violet of the solis appertum. The paper was accompanied by the photographs appeared to the properture of the paper was recompanied by the photographs served by Mr. Smyth in the summer of 185a, and extend to an extreme disance in the invisible violet. The previous observations were included in sixty plates, in the present series, twelve more plates are added in the voilet region, and two independent more plates are added in the voilet region, and two independent tions were included in sixty plates, in the present series, twelve mere plates are added in the wolfer region, and two independent mere plates are added in the wolfer region, and two independent agree with those of Prof. Rowland in microting that the Fraun holder line, "third it of "is either entirely absent now from the solar spectrum, or has become very asimportant.—Mr R. Kid son read a paper on the foreity institute of the Klimatrons, Cultion, are described in the paper belong, with one exception, to the Lower Coal measure.—Prof. That communicated the second and third parts of a paper, by Prof. C. G. Knott, on some relations between magnetism and twent in roon, nacke, and colabilities that the produced in the magnetism that were the combined influence of circular and longitudinal magnetizations. A rectangular roof of cohait twists, like nucled, lelt-handedly, not not the complex of the comp low heids, twist most when the current is reversed. Hystereshs were yether in all the phenomena Evotement sever in this given in Part I., for the twist in terms of the elongations in a thin walled tube of given radius. Part III contains a discus-sion of the magnetic consequences of twisting a magnetized wire —more, especially a circularly-magnetized wire. The peculiar manner in which the magnetic change sometimes lags behind the stress, sometimes shoots ahead of it, is fully investigated. This effect is found to depend upon the strength of the current, on the amount of the twist, and on the amount of vibration to which the wire is subjected. The longitudinal polarity which water the write is subjected. The configuration is country when it acquired when a wire carrying a current is twisted appears to be high in comparison with the intensity induced at the circumference of the wire. This seems to indicate the existence of molecular groupings which alter their configuration when subjected to change of stress or of magnetic force. The effects when the configuration when the configur which are observed when an apparently demagnetized wire is which are observed when an apparently demagnetized wire is subjected to twist suggest that magnetized wire may in certain circumstances consist of alternate layers of opposite polaritate. Any stress which acts differently on these layers will produce powerful magnetic effects. From his own experiments and those of other observers, Dr. Kaott concludes that the first effect of a shearing stress on the molecular groupings is not only to increase the average intensity in the direction of the magto increase the average intensity in the direction of the mag-ienting force, but also to bring isto promisence a relatively high intensity in directions at right angles to it—IP. Buchan commanicated a paper by Mr R. T. Gomod's Appentications to between, on the winds of Ben Neils. The exact determination observer, on the winds of Ben Neils. The exact determination of northerly wands is not very early, owing to the shape of the hill. The cliff, 2000 feet in height, which forms the squally and succertain. Some may be entered on the record or north-west. Somethern winds are on the whole slightly more as north when they should really have been entered as north-east, ontenth-was, Southern wands are on the whole slightly more frequent than northerly winds are. At sea-level the most frequent wand is west, and south-west, west, and north-west include nearly half of the total observations—more than half of calms are excluded. These low-level winds are in exact according to the control of the con

ance with the distribution of barometric pressure over the British Isles according to the Buys Ballot's law, which asserts that British lates according to the Buys Ballot's law, which asserts that the winds blow counter-lockwase round areas of low pressure, such an area lying to the north of the British Isles. But the Ben Nevis winds do not fit in with such a distribution of pressure at all, which indicates that isobars drawn at the level of Ben Nevis (4400 feet) have directions differing entirely from the directions of sea level isobars. In other words, the distribution of average arometric pressure which extends over the North Atlantic an North-western Europe, and dominates the surface wind over that area, does not in this country extend to a vertical height of one area, aces not in this country extend to a vertical neight of one mile. Precaultions were taken to make certain that this difference was not due to a difference between the methods of observation at Ben Nevis and at low-level stations. If a cyclonic storm of small area is jying to the north eastward, the sea-level winds are west or north-west, but the Ben Nevis winds may be north-east, blowing straight out from the centre of the area of low pressure. In larger storms the Ben Nevis winds are practically identical with the sea-level winds, which indicates that a storm has a vertical extent proportionate in some way to the horizontal area which it covers fhe outflowing wind seldom or never occurs when the centre is to the south or west, but only when it is to the north or east, and it is most s'rongly marked when an anticyclone lies on the other side. The outflowing current seems to carry the ascending air of the cyclone to the descending anti-cyclonic regions The non-observation of the outward current c regions when the centre of the cyclone lies on the south or west may be due to the fact that it passes at a higher level than the top of the mountain, for it thea consists of air passing from hotter to colder regions, which will presumably rise to a higher level. The veering of the wind at great heights, which should occur according to the usual theory of cyclones, is very rarely observed. —Dr Crum Brown read a paper, by Dr A B Griffiths, on the blood of the Invertebrata.

CRYSTALLOGRAPHY

Elements of Crystallography for Students of Chemistry, Physics, and Mineadogy By George Huntingdon Williams, Ph.D., Associate Professor in the Johns Hopkins University Second Edition, Revised, pp. 246, with 383 Woodcuts and 2 Plates (London: Macmillan and Co, 1890)

THE position which crystallography ought to occupy in a scheme of scientific education is far from belog generally recognized. Every day the impligit and performance of the property of the p

If we take any standard treatise on physics, we shall find that the subject of the measurement and calculation of crystal forms is almost, if not entirely ignored, and though it is, of course, absolutely impossible to discuss optical and other physical phenomena without reference to the wonderfully suggestive relations which exist between the properties resulting from internal molecular structures, and the crystalline forms which are the "outward and visible sign " of such molecular structure, yet the references are usually vague and, not unfrequently, misleading In confirmation of this statement, it may be mentioned that in a very widely-used treatise on physics -one that has passed through many editions in this and other countries-there is a hopeless confusion between the terms "hemihedrism" and "hemimorphism" in the account which is given of the remarkable phenomena of pyro-electricity.

Nor, as a rule, have chemists dealt more adequately with the subject of crystallography than their brethren the physicists. In many chemical treatises we find such terms as pyramidal, pirsmatic, octahedral, rhombodal, &c, employed so loosely as not to give the student the faintest idea of the real symmetry of the forms which are referred to. This neglect of crystallography by chemists is seen to be the more senious when we remember two important circumstances—first, that crystallization is often the only means which chemists possess of isolating and readily distinguishing many bodies; and secondly, that new substances are being continually formed by the chemist, the study of some of which may throw new and important light upon crystallographic principles.

Mr Fletcher, in a very suggestive address to the Mineralogical Society, has justly remarked —

"Hitherto, at least, the chemists of this country have been too content, either to leave the crystalline forms of their artificial products undetermined, or to impose the ake of their determination on the already sufficiently determined to one of the already sufficiently factory, system of education every chemist should be taught how to measure and describe the crystalline characters of the products which it is his fate to call into characters of the products which it is his fate to call into existence. A Kowledge of the elements of crystalline graphy, including the muchanics of crystal-measurement, at every University."

The consequence of this neglect of crystallography by physiciats and chemists has been that the teaching of crystallography has fallen almost entirely into the hands of mineralogists and geologists. But there is no more reason why every book on mineralogy should commence with a crystallography terusities, than that it should include dissertations on refraction or articles on chemical analysis. "Crystallography should be taught as a special subject," and the student who, after his training in physics and chemistry, takes up the subject of mineralogy, ought to know at least as much of the measurement and symmetry of crystal forms, as he does of the effects of various media on different kinds of radiant energy, or the reactions of the several bases and acids

It would be easy to show that, much as mineraloguists have done for the study of crystallography, the latter scenec would have been developed more logically, and perhaps more rapidly, if the illustrations of the phenomena of crystallusation had not been so exclusively sought among natural products. We find not a few examples in the terminology of the science of the effects of this one-sided growth of crystallography.

Crystallography is based upon purely mathematical considerations, and the study of the principles of crystal-measurement, the discussion of crystal-symmetry, and the calculation of fundamental forms, ought clearly to be one of the first branches of applied mathematics to be taken up by the student of physics; thus the study of crystallography should certainly precede that of physical optics. If this course were followed, the student of chemistry and mineralogy would come to the teachers of those sciences with such an amount of prefuminary information as would enable him to profit by their instructions.

In the work now before us, Dr Williams fully recognises the importance of the principles for which we have been contending, and has endeavoured to supply Englishspeaking students with a short and clear treatise on the principles of crystallographic science. It is certainly emarkable that the countrymen of Wollaston, Whewell, and Miller should have had to wait so long for a work of this character; though every student of the subject must subject must gratefully remember the aid afforded by the admirable little primer prepared some years ago by Mr. Gurney, and published by the Society for Promoting Christian Knowledge.

of Dr. Williams's qualifications for undertaking a work of this kind it is unnecessary to speak. His numerous original researches afford abundant evidence of his devotion to crystallographic study, and in the preparation of the work he has had the advice and assistance of one of the first crystallographers of the United States, Prof. S. L. Penfeld, of New Haven

In order to keep the work within the smallest possible limits, it has been restricted to geometrical crystallography, but otherwise the work has been modelled upon the same lines as Groth's standard work, "Physikalische Krystallographie" The plates and very numerous woodcuts afford the greatest possible aid to the reader, and the typography leaves nothing to be desired. In looking through this revised edition, we are struck with the almost entire absence of those typographical errors that are one saily creep into a work of this kind, and which, though so obvious to an expert, often prove to be a source of infinite trouble to the beginner.

In dealing with the vexed question of crystallographic notation, we think Dr. Williams has exercised a very wise discretion. The simple and easily understood symbols of Naumann have been employed in the first instance, but in almost every case the corresponding symbol of Miller's system has been added in brackets. While all students of physics, chemistry, mineralogy, and geology ought to equip themselves with such an amount of crystallographic knowledge as may be derived from the study of this book, only a very small proportion of them are likely to be called upon to deal with the higher and more complicated problems of the science The small minority of students who devote themselves to purely crystallographic researches may be fairly recommended to employ from the first the beautiful method of notation devised by Whewell and perfected by Miller: but it is more than doubtful if the student with a smaller amount of mathematical training would gain any real benefit from such a course. In an appendix, "on zones, projection, and the construction of crystal figures," the author of this work has indicated to such a beginner the nature of some of the methods of investigation which are pursued by more advanced students.

In any future edition of the work—and such, we feel sure, will certainly be called for—we think that the author would do wisely to add a table showing the symbols of the chief forms according to all the different systems of notation commonly employed. The student who turns to the classical memors of Des Closzeaux, Mallard, Bertand, and others of the French school of crystallography, would thus be enabled to avail himself or much valuable literature, which, owing to the employment of an unfamiliar notation, must otherwise remain a sealed hook to him.

We have spoken regretfully at the outset of this notice of the general neglect of crystallographical studies; but we are compelled to admit that, for this neglect, crystallographers themselves are largely to blame The confusion produced by numerous rival systems of notation is answerable for much of that feeling of despair among those who attempt to make themselves acquainted with the subject. If the time has not yet arrived when a uniform crystallographic language can be agreed upon, much might be accomplished if the plan adopted by the author of this work of giving in every case the symbols according to fwo systems were followed. This is already done in the Zeitschrift fur Krystallographie, the Neues Jahrbuch fur Mineralogie, &c , the Journals of the English and French Mineralogical Societies, and several other wellknown periodicals If a conference of the leading crystallographers of Germany, France, and England could be held to decide upon the order in which the axes should be aken in writing symbols and other similar arrangements which are purely conventional and arbitrary, we might hope to see much of the confusion removed that has so long been a bar to the progress of this most fascinating and important branch of science

We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography. The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to unlearn.

JOHN W. JUDD.

PHOTOGRAPHY IN COLOURS.

Photographie des Couleurs par la Méthode Interférentielle de M. Lippmann. By Alphonse Berget. (Paris . Gauthier-Villars et Fils, 1891.)

THIS interesting little brockure contains an account of the recent achievements in colour photography which have been made so widely known to the English public through the daily papers. Coming from the pen of an "attaché au Laboratoire des Recherches (Physique) de la Sorbonne," we may take this contribution as an authorized exposition of M Lippinann's work, and as such it will be found useful by physicists, chemists, and photographers, as well as by the general reader who wishes to know the real state of the case concerning this important departure in photographic methods. In a short historical introduction the author calls attention to the previous photochromatic attempts by Seebeck in 1810, by Herschel in 1841, by Edmond Becquerel in 1848, by Niepce de St Victor in 1851 to 1866, and by Postevin in 1865. It is stated that these and all similar attempts were based upon purely chemical methods, the investigators seeking for some sensitive compound which would give chromatic impressions corresponding to the colours impinging on the film M. Berget adds the important remark "a priori, ce problème est irréalisable "

Chapters is to v are devoted to elementary optical principles. Chapter ii. deals with vibratory movements and their propagation, wave-length and period, and sonorous waves. In the third chapter the phenomenon of interference is described and explained; in the fourth chapter we have sections on the luminiferous ether, the velocity of light, the decomposition of white light by a prism, and Fresnel's theory of the spectrum colours The subject of complex colours, as distinguished from the pure colours of the spectrum, is also dealt with in this chapter, and is of special importance in connection with the colours of natural objects, to which the author devotes a short section. It is pointed out that the principle of superposition of vibrations holds good in optics as in acoustics, and that just in the same way that the diaphragm of a phonograph can take up and faithfully transmit the extremely complex system of superimposed aerial vibrations produced by the human voice, so the ether transmits the complex superimposed vibrations emanating from coloured objects. In connection with the history of the undulatory theory, the whole credit is given to Fresnel: "L'honneur de donner la première théorie rationelle de la lumière, en la considérant comme résultat d'un mouvement ondulatoire, était réservé à un savant français: Fresnel" We should like to have seen Thomas Young receive at least an honourable mention

The subject of interference receives more detailed treatment in chapter v, the interference of direct and reflected waves, and the theory of Newton's rings, being specially dealt with. It is not till we come to the sixth chanter that we are introduced to the main subject of the brochure. The principle which guided M Lippmann in his experiments is well and tersely given. Imagine a plane metallic mirror with its reflecting surface coated with a transparent, homogeneous film of a silver haloid in albumin or collodion. Supposing a coloured ray of definite wave-length to fall on such a film, the undulations would traverse the transparent sensitive film, and being reflected from the polished surface of the mirror, and meeting the incident waves, would produce interference The snace in front of the mirror would thus be occurred by parallel planes alternately light and dark, and separated by half wave lengths, i.e. by spaces of 1/4,000,000 of a millimetre. Phere is therefore aimple space, even within the thickness of the film for several of these planes of interference On development, the planes corresponding to the light intervals would alone give films of metallic silver, while the dark intervals would remain unaffected On fixing, there would thus be left in the film a series of parallel films of metallic silver separated by half wavelengths Any pair of such films constitute a thin plate in the Newtonian sense, and will give by interference a colour corresponding to that which produced the original deposition of the filins when viewed by reflected light,

To realize the foregoing principle experimentally, M Lippmann has found it necessary to use dry films of collodion, or albumin, or relating sensitized by immersion. as in the old wet collodion process; emulsions are granular and opaque, and contain particles which are gross in comparison with the half wave-length of a spectrum colour, and cannot be used. Moreover, it has not been found practicable to coat the reflecting surface of the mirror directly with the sensitive film, because the free todine tarnishes the silver and destroys its reflecting power. This difficulty has been surmounted by making the coated glass plate one side of a shallow trough with parallel sides filled with mercury, the coated side being inwards, and in close contact with the mercury The conditions for reflection and interference are thus fulfilled. The image of the spectrum is focussed on a glass plate with a ground surface, which is temporarily fixed to the side of the cell or trough in the same position as that occupied by the sensitive plate, i.e. with the ground surface inwards. After focussing, the ground glass is removed, and the sensitive plate substituted for it in the position described

The spectrum was produced by an electric arc light of 800 candle-power, and the time of exposure for the different parts of the spectrum was regulated by interposing cells with coloured solutions, beginning with a solution of helianthin which transmits only the red and yellow, then replacing this by a cell of potassium dichromate which transmits the red, vellow, and green, and then finally exposing for a few seconds without any screen, so as to impress the blue and violet. The whole time of exposure varies, according to the sensitiveness of the film, from half an hour to two hours. The details of development and fixing are given by M. Berget, and do not differ fundamentally from the ordinary methods.

The finished image, when dry, shows the spectrum colours by reflected light with metallic brilliancy, and as the colours are purely optical, depending only on reflection and interference, they are permanent. As the author points out, it is certainly a marvellous tribute to the fidelity of the photographic method that a series of laminæ of metallic silver separated by intervals of only about 1/4,000,000 of a millimetre should retain their positions with optical accuracy during the processes of fixing and development

There can be no doubt-as will be admitted by all who have seen the results-that M Lippmann is to be congratulated on having made a most important advance in the methods of photochromy. How far his experiments go towards the realization of the great problem of photographing objects in their natural colours is a question quite distinct from his present achievement. M. Berget tells us that satisfactory reproductions of coloured glasses illuminated from behind by the electric light have been obtained, but this is only a very little step in the desired direction

"One reste-t-il à faire pour rendre absolument usuel le procédé photochromique de M Lippmann?" There remains a great deal! Not the least of the requirements is a transparent sensitive film equally sensitive to every colour of the spectrum, and sufficiently sensitive as a whole to enable the impression to be secured with a moderate exposure, instead of 30 to 120 minutes. Till this is accomplished we are not much nearer the solution of the problem of photography in natural colours than we were before M. Berget speaks hopefully of the prospects in this direction, and we wish every success to his anticipations. But it is no detraction from the merit of M Lippinann's results if these have no immediate bearing on practical photographic processes As a triumph of physical science these experiments will live.

"C'est aussi un triomphe pour la science française, car ce mode de reproduction des couleurs du spectre à l'aide des lames minces limitées par des plans d'argent constitue une matérialisation, réalisée par un savant français, de ces ondes lumineuses conque pour le première fois par le puissant génie d'un autre Français illustre : j'ai nommé Augustin Fresnel."

With this patriotic outburst M Berget concludes his pamphlet, and the compatriots of Niepce and Daguerre may well be gratified with this latest emanation from the physical laboratory of the Sorbonne.

R. MELDOLA.

OUR BOOK SHELF.

Geometry of Position By R H. Graham, Author of "Graphic and Analytic Statics." (London and New York: Macmillan and Co, 1891)

THIS work essays to fill an existing want by providing an English text-book on the important subject of geometry of

position in relation to graphical statics.

The author gives an introductory chapter on anharmonic pencils and ratios, followed by an interesting chapter on projective conics, and devotes the remainder of the book to the application of graphic methods to statical problems including, amongst others, the discussion of Maxwell's theory of reciprocal figures.

The chapter on anharmonic pencils and ratios would have been considerably improved by the introduction, at

the beginning, of more definitions and explanations of the

nomenclature adopted. The proofs of Desargue's theorem and its converse, given on p 3, are unduly compressed, considering the early stage at which they are introduced. and the student's preliminary difficulties will be increased by the fact that the enunciations have been given in succession, while there is nothing to indicate which is to be treated first.

In the chapter on reciprocal figures, we would suggest that the proof given of Theorem I, Art 50, might with advantage have been dispensed with. In Art. 52 it is erroneously assumed that OB' is equal to force (1); this assumption mars a proof which would be otherwise good. The work exhibits evidence of originality, and it is, perhaps, to be regretted that the proof-sheets have apparently been revised only by the author himself. Their revision

by one who had no part in compiling them would probably have contributed to a better arrangement, and to the exclusion of much that is vague.

The carefully drawn diagrams of different problems contained in the book form admirable illustrations to the non-technical reader of the nature of the operations involved in the application of the graphical calculus, and of the character of the results obtained by it They are the more welcome as such information is not readily available in English text-books, while in foreign treatises it is often developed in such minute detail as to make the foundations nearly inaccessible to the general reader

A word of praise is due to the interesting collections of examples at the ends of the chapters, which are, it seems, mostly original, but partly drawn from sources not often laid under contribution in the ordinary text-books ALEX, LARMOR,

The Species of Epilobsum occurring North of Mexico By Dr Trelease, Director of the Missouri Botanic Garden From the Second Annual Report of the Garden, issued April 1891 48 pages, 48 plates

EPILOBIUM is not a very large genus, but is spread universally through the north temperate sone, both amongst the plains and mountains, and reappears in plenty in New Zealand The species are very difficult of delimitation and definition, and great diversity of opinion has prevailed as to their number, and the validity of the characters which have been used to characterize species. It is evident, moreover, that many of them hybridize freely in nature Passing over the earlier well-known writers, such as Pursh, Muhlenberg, Hooker, and Gray, in 1876 Barbey contributed a monograph of the Californian species to Brewer, Watson, and Gray's "Flora of California," and later published excellent figures of the new species which he there described. In 1884, Haussknecht published a there described. In 1004, riau-skinectit published a monograph of the whole genus Of the 53 species dealt with in Dr. Trelease's paper, 13 have been proposed by Haussknecht, 3 by Barbey, 4 by himself, and one by Parish, so that more than half the 38 have been lately described for the first time. Dr. Trelease describes fully all the species known in Temperate North America, gives an octavo plate of each of them, and a detailed account of their geographical distribution, cting the numbers of all the recent collectors. Of the 38 species only 9 extend their range beyond the American continent. The paper will be a very acceptable contribution to our knowledge will be a very acceptance controlution to our knowledge of a difficult genus, and will no doubt be incorporated in the new "Flora of North America," of which the second veglume is already published, and the first and third of which we anxiously wait for J. G. B.

A Guide Book to Books. Edited by E. B. Sargant and Bernhard Wishaw. (London Henry Frowde, 1891) THERE are so many books of all kinds that ordinary readers may be excused if they are sometimes at a loss as to the works which they ought to select for study. The editors of the present volume have come to the aid of such readers, and may be congratulated on the

manner in which they have accomplished a useful but most troublesome task. They make no attempt, in a philosophical sense, to classify the various subjects with which authors have dealt; they simply take these subjects one after the other, in alphabetical order, and set down what seem to them the best books relating to each. Taking into account the amount of space at their disposal they probably could not have chosen a plan that would have been more readily intelligible. Of course opinions will differ about the value of the works included in the several lists. Everyone who consults the volume will be of opinion that the editors have omitted some things which they ought to have noted, and that they have But there cannot but be a general agreement that, upon the whole, the selection has been made on sound principles, and that it is likely to be of real service to very many of those who may have occasion to refer to it. A large number of eminent writers have helped the editors, not only by drawing up lists of books, but by giving them much valuable advice.

Tasmanian Official Record, 1891 By R. M. Johnston, FLS By Authority Second Year of Issue (Tasmania, William T. Strutt, Government Printer, Hobart,

ANYONE who may wish to obtain information about Tasmania will be hard to please if he does not find what he wants in this elaborate volume. It begins with an account of the general physical outline of the island, and then we come to Tasmanian history, and to the Tasmanian constitution and government. After a chapter on Crown lands we are invited to consider the geology and mineral products of Tasmania, its flora and vegetable products, fauna and animal products, population, vital statistics, law, crime, and protection, and "intellectual and social provision" The work is wound up with a view of the proyress of Australasia, and a summary of general statistics. In the present issue some important additions have been made to the book as originally published, and by devoting attention to classification the editor has tried to "obviate any difficulties that might arise from the necessity of bringing together in one volume such a

The Albert University.

PROF. LANKESTER, in the interesting letter published in NATURE for May 28 last (p 76), expresses his desire to have 'a genuine professorial University set on foot in London, not because it is London, but because University and King's Colleges are there, and respectfully petition Her Majesty to do for them what the monarch has done in past days for other Universities '

Universaties."

I have not seen the petition of the Colleges. But I have before me the draft charter adopted by their Councils, which I presume Is insteaded to give effect to the prayer of the petition. I can hardly imagine that Frof. Lankester was acquisited with I for the present of the petition. I can bardly imagine that Frof. Lankester was acquisited with I fifth Albert University of London was in the theory of the petition of the petitio

NO. 1131, VOL. 44]

commending to its students systematic courses of teaching and methods of study." But "commending" is what we all do now.

all do now.

The new University is to be of the federal type Beginning with University and King's, "other Colleges may from time to time be admitted." This was inevitable, though my pointing out the fact made my friend Prof Laukester somewhat angry. out the fact made my friend Prof Laukester somewhat angry.

Any medical school may be admitted which is recognized as

efficient by any qualifying body under the Medical Acts. But
while Colleges will have representatives on the Council, the
medical schools will only have representatives on the Faculties

menuma scucous will only have representatives on the Faculties Degrees may be granted apparently in any subject the Council please, subject to a regular course of study and examination This will apparently admit theology, which is probably a desirable thing, provided it be unsectarian.

destrable thing, provided it be unacctarian.

The powers to grant degrees are rather large, and deserve careful consideration. The London radius at once, as has been the case with the existing University, goes of into Imperainfinity in the provision that anyone who has been a resident student in any University in the Empire may count his time and examinations, except that a "final portion of the period of study" and the "final examination" shall be passed in the

University. There is an unlimited power to grant ad eundem degrees as I nere is an unimited power to grant an unation degrees as well as honorary degrees at the discretion of the Council. Fellows of University and King's Colleges (a purely honorary distinction in itself) are indicated as fitting recipients, and also "past students of the said Colleges," a rather large door to open if in the future a degree is to have any meaning at all

Power is taken to examine into the efficiency of schools or any academic institutions-work already in the hands of other Universities-and apparently the London radius again becomes

Independent University lecturers may be appointed Independent University tecturers may be appointed
The Council will consist of members appointed for five
years by (1) the Crown (Lord President), (2) Convocation,
(3) Colleges; (4) Colleges of Physicians and Surgeons, (5)
Faculties
The Faculties are to be constituted (1) of teachers Faculties The Faculties are to be constituted (1) of teachers in the Colleges, (2) of examiners, (3) of persons who are or have been engaged in University teaching in London The Boards of Studies are delegations from the Faculties, as they should be. All this is much on the lines sketched out in my own letter in NATURE

A rather remarkable feature in the scheme is the creation of Convocation of graduates Whatever may be the function of this body in other Universities, it is somewhat surprising to meet with its existence in what profesions to be a teaching University

The examinations are to be conducted by examiners who a members of the respective faculties associated with external examiners, the teacher examiner seems not to be insisted upon These are the essential elements of the proposed constitution.

If it is asked what distinctive character the Albert University If it is asked what distinctive character the Albert University will possess which will mark it off from the existing University, or from that body as it might be conceivably reconstituted, I must confess that it seems to me to lie in a very small compass. Notwithstanding the use of the ambiguous word "commending." Notwithstanding the use of the ambiguous word "commending," when one would have expected "prescribing," I take it for granted that the essential feature in the whole scheme is the granted that the essential feature in the whole scheme is the enforcement upon candidates for degrees of attendance upon a curriculam. But in the existing University, this is already required in the Faculty of Medicine. Frof Husley has further urged it in the Faculty of Science, and for my part I believe that the time has arrived when it might be demanded without difficulty. The prominence given to practical work in the science examinations has made it all but impossible for a canscience examinations has made it an out impossion of a tended didate to acquit himself successfully who has not attended a competent course of instruction. To insist upon a currididate to acquit himself successfully who has not attended a competent course of instruction. To insat upon a curri-an competent course of instruction. To insat upon a curri-nuiton of this fact. The only real point of divergence as in miles of this fact, and the fact of the present of a curriculum is desirable; I am may be that the enforcement of a curriculum is desirable; I am the properties of the control of the control of the control of the execution, at I think it is in the Faculty of Scence With this execution I can see no not public gain in the new scheme to partly the creation of the cushroos machinery of a new federal University.

Seeing that the existing University is a State institution in actual possession of the field, I think the public at large might

have reasonably expected from the Senate some statesmanlike criticism, rising above the petty level of supposed self-interest in the very serious action which the Government is apparently about to take

197

to take. They content themselves, however, with a sort of half sulky acquisesome in the scheme "so far as it proposes to confer on the pertonage College the power of grauming digrees in a sure that the scheme of placing the power of granting degrees in the hands of those naturally insists upon the inconsistency with this position of the proposal "to accept resistence and examinations at other un-versities," if only a final period of study, "which might be a short attendance at evening classes," be passed at the new University It also objects to the honorary and ad cundem degrees But

It also objects to the honorary and ad candem degrees. But its criticism is even more destructive in regard to the Medical Schools. It is quite obvious that if the Medical Schools joined the Albert University, the teacher-examiner system would disappear, and the new and the old Universities would be simply competing agencies for doing the same kind of work in the same kind of way The same argument applies more or less to the other faculties as soon as the number of constituent Colleges becomes numerous

Yet so great is the magic of a phrase that the daily papers in reporting the proceeding, in the Privy Council describe the scheme as that of a Teaching University A University of the Scotch or German type may have some claim to that title, but no federal University can ever possess a valid one, for the simple reason that there will always be a morphological distinction between the Colleges which teach and the University which

examines and grants degrees
Prof Lankester contended in his letter that the question whether University and King's Colleges should have a University Charter was a sort of private affair between them and the Govern nient But I do not think this view can be accepted ment but I do not taink this view can be accepted whether we like degrees or whether we do not, they have a certain value in the eyes of the public Personally, I have no objection to the multiplication of Universities, if each has a proper geographical area assigned to it. But the multiplication of Universities in the same place seems to me a great evil It cannot be assented to without the necessity heing shown to be overwhelming. in the present case it appears to me that it cannot be so shown If the existing University is so injurious to the best interests of the higher education that another is imperatively demanded to do the work in which it fails, then it appears to me that two obvious points pre-ent themselves —

(i) The new University should be free from the defects that

attach to the old one Prof Lankester speaks of the "thraldon" of "the Imperial centralizing institution", but when the matter comes to be looked into, the new institution also proposes to be Imperial and centralizing, and will be found to exercise the same or even greater thraldon on the individual teacher

(2) If the old University is really doing mischef, it is the paramount duty of the supreme Government, whose creature it is, to reform it. The fact that the Senate and Convocation are to reform it The fact that the Senate and Convocation are at loggerheads how this is to be effected is really beside the When public opinion demanded the reform of the older Universities, new ones were not created alongside the unreformed old ones, but a Commission with executive powers reformed old ones, but a Commission. And for a simil effected the changes which were necessary. And for a simil procedure there is still time at Burlington Gardens.

W. T. THISELTON-DYER. And for a similar

The Holarcuc Region

RFYLEWING the recently published "lattroduction to the Study of Mammals" by Prof. Flower and Mr. Lydekker, Prof. Landester state (gryd, p. 12) Jahn. "The nuthors of the present Landester state (gryd, p. 12) Jahn." The nuthors of the present Nearctic regions should be united and called the Flohrect region. But they do not adopt this opinion, nor refer to Hude'y proposal to term this same area. Arctogras," and so on. Now, is this last statement my good friend the reviewer, perhaps willing from memory, is mistaken. Had Irof. Hude'y proposed to Inteln this "Arctogras" to the Falsaractic and

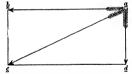

Nearctic regions of Mr. Sclater and Mr. Wallace, I should certainly not have suggested to Prof. Helipme a new name for that combination. Anyone booking. On the prof. Helipme a new name for Mringle (defined his "Arctogea."—a name to which, let me say, I have not the least objection—will see that it signifies that part of the world which is not "Notogea," and therefore includes the Ethiopian and Indian regions of Mr. Solter, whereas my "Holascic." region expressly excludes them, and is therefore a very different thing from "Arctogrea" in its true sense.

ALFRED NEWTON. Magdalene College, Cambridge, June 12.

Force and Determinism,

In your issue of March 12 (vol alin p 491), Dr. Oliver J lay your issue of March 12 (vol altin p 401), Dr. Oliver J Logic characteries as "perfectly corrected to streement "that, logic characteries as "perfectly corrected to the content of matter, none is needed to alter its direction." I have looked in vain for some notice of this apparently strange doctrime in your subsequent issues, with the exception that Frof C. Lloyd Morgan (April 16, p. 58) objects that the direction of motion only the observation of the content of the motion of the content of t

ncrease the speed of matter ". But, as a matter of fact, is it not very difficult, in not indeed practiculty impossible, to change the direction of a moving body without affecting its speed? "A force at right angles to motion does no work," says Dr. Lodge Let us examine this statement for a moment. Let a body be moving in the direction a to 8 with a speed sufficient to traverse the distances in one unit of time. Then let a force be applied to

the body at a, at right angles to the direction of its motion, the body at a, at right angles to the direction of its motion, sufficient, if accurage alone, to carry the body to of an the same unit of the unit of time, would, therefore, be found at c. But the distance at a greater than ab, and as, by the interposition of a force at right angles to its motion, the body has thus inversed a force at right angles to its motion, the body has thus inversed as of fact, been increased a fand in on this increase of peed actual work? and does not this work require actual energy to perform at 10 works IIS A lives.

EVAN MCLENIAN.

Brooklyn, Iowa, U S.A , June 9.

I AM glad to see my statement called in question, and hoped that it would have aroused more antagonism than has yet been expressed; because I do believe that it has important psycho-logical or metaphysical consequences, and should therefore either be repudiated by physicists or after due discussion be accepted by non physicuts.

With regard to the special objection raised by Mr. McLenns

With regard to the special objection ranged by art, melannam, it may be sufficient to remark that, in his diagram, at is the line of motion, ad the direction of the force, and that ad is not at right angles to ac. His difficulty seems to be the one that some people always feel with regard to the use of infinitesimals in general. He must remember that his diagram will not apply

to the case of curvilinear motion unless the impulses contemplated are momentary and infinitesimal. OLIVER J. LODGE

The Scorpions at the Zoo.

YOUR contributor of the notice, published in NATURE on June 18 (p. 163), on the contents of the Insect-house at the Zoo, who laments the unfortunate circumstance that the scorpions there in captivity remain unnamed, may be glad to learn that these creatures may be easily identified, and, with a little dex-terity, fearlessly handled

During a recent visit to this house, the keeper obligingly showed me the two Egyptian scorpions, one of which—the black individual with the thick tail—was easily recognizable as Prionurus crassicauda, Oliv., a tolerably common North

African and Syrian form

Afracan and Syram form 1 could not so readily assign a name; 1 to the other, however, 1 could not so readily assign a name; 1 to the other, however, 1 could not so readily assign a name; 1 to the country of the count

qualitying for incarceration in Biolians, fastily interposed when Larteched out my hand to pick up the noxious animal. The third scorpion I did not see, but doubtless it is a fast to be a seed of the seed of t another genus is before them

another genus as before them In conclusion, some of your readers may be interested to know that the spider referred to as Lyona portosantana—which, by the way, should be styled Tarantula mader ana—is a very near ally of the famous and historical Tarantula of Italy, and that the harry Brazilian monster, the so-called Mygsle, who squats under a broken flower-pot in the next cage, has no more claim to the title Tarantula than any other Arachnoid with a formid-R I. Cetaceans in African Lakes,

Wirst reference to Mr. Schter's inquiry (NATURE, June 11, 124) as to the occurrence of porposas in the Victiona Nyanza, the following extract from Bernier, who wrote about 230 years ago, will probably prove of inteest

I may add that in another passage Bernier gives further in formation regarding the sources of the Nile

It would seem from the passage quoted that the occurrence of At WOURD SCHOLLING THE PRESSAGE QUOTED that the occurrence of a Cetacean in the Abysinian sources of the Nile was probably known to early travellers, and, like the occurrence of chamonds in other parts of Africa, cannot be regarded as a new discovery Science and Art Museum, Dublin, June 22.

ON SOME POINTS IN THE EARLY HISTORY
OF ASTRONOMY

V.

It is imperative to be perfectly definite and clear on the question of the amplitudes above 20° at Thebes. Any amplitude within 26° means that up to that point the sun at surners or sunset could be observed some day or days of the year—once only in the year if the amplitude is exactly but the case of these temples with greater amplitudes than 26°, it is quite clear that they can have had nothing to do with the sun. Is there, then, any additional line of evidence that the Egyptians used these temples to observe a temple but at one period to observe a star could not go on for ever serving its purpose, for the reason that the declination of the star must change by precession Therefore a temple but with a particular amplitude to observe a particular star, useful for one period would be

We have here possibly a means of testing whether or on any of these temples were used to observe the stars in those very early days, 5000 or 4000 years it.C., we must assume that the people who observed the stars had not the slightest idea of these possible precessional changes; they magned, that they were just a safe in directing a temple to a star as they were in directing a temple to the sun but with a star changing its declination in an average way, the same temple could not be used to observe the end of that time, I they still wheel for a sheet that the truther star, they must either change the axis of the old temple, or build a new one

As a matter of fact, we find that the axes of the temples have been changed and have been freely changed, that there has been a great deal of work done on many of these temples which are not oriented to the sun, in order to give them a twist

Once a solar temple a solar temple for thousands of

Once a solar temple a solar temple for thousands of years; once a star temple only that star temple for something like 300 years, so that the conditions were entirely changed

We get cases in which the axis of a temple has had its direction changed, and others in which, where it has been difficult or impossible to make the change in a temple, the change of ampitude has been met by putting up a such temple as a series in which instead of changing the orientation of a pre-existing temple, a new temple has been built to meet the new condition of things. That, think, it as suggestion which we are justified in making to

Egyptologists on astronomical grounds
We cannot, of course, make it with absolute certainty, for the reason that in the case of most of these temples the best Egyptologists cannot give us the most precious piece of information which we require from the astronomical point of view. That is the date of the foundation of the temple. If in the case of these temples it were absolutely certain that each temple was built at a certain time with a certain orientation, the use of the precessional globe would tell us at once whether or not that temple was pointed to any particular star. Some other astronomical considerations may here come to our help. If the north polar distance of a star is increasing-that is, if it is increasing its distance from the north pole-its declination is being reduced, and the orientation of the temple would be gradually becoming more and more parallel to the equator; if the declination of the star be increasing, then the orientation of the temple would have had to be more and more north or south The change in the orientation, therefore, could give us important

' Continued from p 110

information, and ultimately we might be able to determine what the name of that particular siar was. At present the matter must remain more or less as a suggestion; but if anything like approximate dates can be given, then astronomy really may come to the rescue of the Egyptologist and archæologist generally, and repay that deb to which I have referred, which she owes to so many other

Although, however, these matters can be discussed in a way that will indicate that the inquiry is raised, I do not wish for one moment to speak of it as being settled, because the observations which have been made already in Egypt with regard to the orientation of these temples have not been made from such a very special point of view; and further some alteration in the amplitude would be made by the presence of even a low range of hills miles away from Thebes in the case of a star mange or setting pretty menty north or south. No

Fig. 14 -The two temples at Medinet Abos, showing the change in their

one would care to make the assertion with absolute definiteness until a was known whether on not the horizon in each case was interfered with by hills or any intervening objects—was or was not one, in fact, which might be regarded as a sea horizon from the point of observation; if there were impediments, the angular height of them must, of course, be exactly known.

To continue this observation and this kind of thought

To continue this observation and this kind of thought a little further, we will go back to Karnak generally. In the first place we have the magnificent solar temple.

Next we have two parallel temples, one of them a late addition to the solar temple itself, and another one parallel to it, each of them with an amplitude of 63°, one N. of E., the other S of W We have then two parallel temples at right angles to the solar temple at Karnak We have also a temple, with an azimuth of 68° N, of E., and one, probably older still, with an amplitude of 8° N, of E., and one, probably older still, with an amplitude of the solar parallel temples at right and the solar parallel temples, one of them is a simple to the solar parallel temples, one of them is a late of 50° N. of E., and one, probably older still, with an amplitude of the solar parallel temples, one of them is a late of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one, probably older still, with an amplitude of 50° N. of E., and one probably older still, with an amplitude of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with an amplitude of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of 50° N. of E., and one probably older still, with a manife of

tude of 70° or 71° N of E; both these temples face norberly, and nearly in the same direction. Near the last temple we have the runs of another one at night angles to the difference of the points so the received and plan of the runs that the Naos 1s at the east end of the temple, therefore the chief plyon would have been to the west, and therefore the axis will be in that direction, the state of the contraction of the truns that the Naos 1s at the east end of the temple, therefore the chief plyon would have been to the west, and therefore the axis will be in that direction, the state of the temple of the truns that the Naos 1s will be in that direction, the property of the temple of Maist and Karnak, the line is absolutely complete as far as their bases are concerned, with the exception of two where there is a gap, and that gap is exactly in the axis of this temple prolonged. Here is another being strictly reserved.

The Egyptians have been accused of hating every regular figure, and even in the boundary walls of the temple of Ammon there are two obtuse angles Rousel had the Maut temple we also have walls, and there again this hatred of anmiarry seems to come out, for we have a little carefully, we find that there is a good deal of method in this apparent irregularity. The wall of the temple of Ammon is parallel to the face of the temple of Ammon is parallel to the face of the temple angles to the sphinnes. And the reason that we do not get right angles at one end of the wall is that the walls of the temple of Ammon. Surely it must be that, before these accombined worthing, that they stood or fell together. One thing was not attempted in one temple and another thing in another, but the worthin of sach was reflected in the other. Am of this bettue you see that there was

We can depend, and no doubt depend very completely indeed upon the labours of the Egyptologists, in the case of the temples of Ramsess and of Khons No Egyptologists of Egyptologists, in the case of the town of

Was there an important star with a declination of 53° N, m, was there another with a declination of 53° N, in the year 1200 BC.? There were two important stars, one with a declination of 53° N, and another of 53° S, at that time The north star was p Dracons, the south star was Canopus This strengthens the view that there was really some astronomical object in the plan and direction of these temples

Thus, at the time when these two temples were stated to have been built, each might have been suited to observe one the raing, the other the setting, of an important star. We have long ago seen that so far the Egyptians, like the Babylonians at a later date, only had an idea of observing a heavenly body and the position of other bodies in relation to it, so long as it was raing or settings, so that it was absolutely essential that the body which they were to observe should rise and set. You know perfectly well that in London there are many being \$1°, the elevation of the pole therefore a \$1°, and from the pole to the north point of the borron being \$1°.

of course any star which lies at that distance from the pole eannot set, but sweeps round without touching the horizon at all. The latitude of Thebes being 25°, the distance from the pole to the horizon is much smaller, and so the number of stars which do not rise and set is much smaller. The stars which did not rise or set were stars which were moving very slowly and the stars which rose most to the north and most to the south were those nost to the north and most to the south were those bodies which were moving most slowly while they yet rose or set Can this slow rate of motion have bad anything to do with such stars being selected for observation, the brightest star to the north, most slowly moving, the brightest star to the south most slowly moving? It is possible that observations of these stars might have been made in such a way that at the beginning of the evening the particular position of γ Draconis might have been noted with regard to the pole star, if there were no other reason, and seeing that the Egyptians thoroughly knew the length of the night and of the day in the different portions of the year, they could at once the moment they got the starting point of the rising of this star practically use the circle of the stars round the north pole as the dial of a sort of celestial clock May not this really have diat of a sort of celestral clock way not this really have been the clock with which they have been credited? However long or short the day, the star which was at first above the pole star, after it had got round so that it was on a level with it, would have gone through a quarter of its revolution

So much then for the possible use of the temples built by Ramess III in the year 1200 in C I has already been pointed out that although we have in one an amplitude of 65 N of E we have other temples with amplitude of 65 N of E, and 71 N of E. Everybody agrees that the temple, with amplitude 69 N of E, was built 1200 years in C. I have shown that that temple could have shown that that temple could have a transfer of the temple and the 71 temple were temples built to observe the same star the fort this one was built, because we know they could not have observed the star after this one was built, since y Draconis us december 18 declination, therefore in previous times its declination would have been higher, and the amplitude therefore of a temple to observe it would have been

Looking back to the German tables and other calculations, we find that with an amplitude of 65° we get a declination of 56°, and the same tables tell us that that declination of 50°, are the same tables are y Draconis 2000 years BC I tools look as if in all probability we are dealing with a series of temples not twisted

but bulk in different places.

Can we consider that the temple with an amplitude of 71° might have been used to observe that same star long before the temples were bulk with amplitudes of 68° and 63°? The amplitude of 71° gives us a declination of 68° and 64°? The amplitude of 71° gives us a declination of 80° and 64°? The amplitude of 71° gives us a declination of 80° and 64° an

The discussion is a little difficult because the orientation is very far towards the south and north, and therefore a hill a few miles off would make a difference of 2° or 3° in the orientation of the temple, and as yet we have no observations that throw light on this point. We have then at Tbebes alone three converging lines

We have then at Tbebes alone three converging lines of evidence which all go to strengthen the view that these temples were really—whatever else they might have been —usable as solar and stellar observatories. The difference being of course that in the case of the solar temple no large change of amplitude was necessary, but that in the case of every stellar temple after a lapse of a certain number of years depending upon the position of the star, the temple must be twisted round if it were wished to

continue to make observations of the same star. That raises an interesting question by the way. Long after the temple had been used for observation of a particular star, long after that temple line was blocked by extended building, if the horizon of these temples was left open it looks very much as if when another bright star came along it was laid hold of for a new set of observations. However that may be, it is rendered extremely probable, by the considerations I have brought before you, that the Egyptians 3000 years B C had been rendered practically conversant with the result of the precession of the equinoxes by the fact that they had to rebuild and alter their temples from time to time because the stars changed their declination If that he confirmed by subsequent investigations. it will show that these Egyptians possessed a very much more profound knowledge of astronomy than they have received credit for, because it is stated that the precession of the equinoxes was discovered by Hipparchus. It looks as if the precession of the equinoxes was probably published by Hipparchus as the result of an examination of the untold wealth of Egyptian astronomical observations which has been unfortunately lost to the world

This question of orientation is after all one which survives among ourselves All our churches are more or less oriented, which is a remnant of old sun worship, and the church is not always oriented exactly to the east, but so that the light of the sunrising upon the Saint's day to whom the church is dedicated may be thrown along the chancel

It has long been known that Stonehenge is oriented to the rising of the sun at the summer solstice. Its amplitude instead of being 26' is 40'; with a latitude of 51', the 26° azimuth of Thebes is represented by an azimuth of

40° at Stonehenge

The first of January is very near the winter solstice, but is not quite the winter solstice lf you look up the old records of the races that lived 2000 or 3000 years B.C., you will find that the different races began their year at different times, and even that the same race at different times began their year differently, the choice lay among the equinoxes and the solstices, and seeing that one of the very oldest temples at Thebes is oriented to sunset at the summer solstice we should not be at all surprised if investigation shows that when that temple was built more than 3000 years B C., the Egyptian year really began in what we should call our summer We have ample evidence of this And I think there is little doubt that when Stonehenge was built it certainly was built by people who began their year with the summer solstice, which you will remember is the time of the year in which in many countries it is the habit still to light fires upon hills and so on

The next point is, what was probably the use made of these temples besides determining the length of the year and regulating so far as they could the seasonal changes, the times of the solstices, the times of the equinoxes, and

the various celestial phenomena?
We understand that in the very beginning of observations in all countries, the moment man began to observe anything, we saw that he began to observe the stars, and the moment men began to talk about anything they had seen they must have started by in some way or

other defining the particular stars they meant.

They would obviously talk first of the brightest stars, and separate them from the dimmest ones, they would then discuss the stars which never set, and separate them from those which did rise and set; then they would take the most striking configurations, whether large or small; they would choose out the constellation of Orion or the Great Bear, and for small groups the Pleiades' These

would attract attention, and be named before anything else Then later on it would be imperative in order to connect their solar with their stellar observations that they should name the stars which lay along the sun's path in the heavens. They would confine their attention to a belt round the equator rather than consider the configuneit round the equator rather than consider the configu-ration of stars half-way between the equator and north pole. In all countries—India, China, Babylonia, Chaldeza, Egypt—they had a sort of girdle round the heavens, called by different names in different countries, and the use of this girdle of stars, which sometimes consisted of twenty-eight stations, sometimes of twenty-seven, and sometimes of only ten, was to enable them to define the place of the moon or of any of the planets in relation to any of these stars That condition of things, that stage of thought, is brought well before us in the lewish

In the Book of Job we read, "Canst thou bind the sweet influences of Pleiades, or loose the bands of Orion? Canst thou bring forth Mazzaroth in his season? or canst

thou guide Arcturus with his sons?

Here we have the difficulty which has met everybody in going back into these old records, because there was no absolute necessity for a common language at the time . it was open to everyone to call the stars any name they chose in any country, therefore it is difficult for scholars to find out what particular stars or constellations were meant by any particular words. In the revised version, Arcturus has given place to the Bear with its train, and even our most distinguished scholars do not know what Mazzaroth means I wrote to I'rof Robertson Smith the other day to ask him to give us the benefit of his great knowledge, and he says that Mazzaroth is probably that band of stars round the ecliptic or round the equator to which I have referred, but he will only commit himself to the statement that it is a probable enough conjecture, other people believe that it was a reference to the Milky

I mention this to show you how very difficult this inquiry really is The "seven stars" undoubtedly mean the Pleiades and not the Great Bear Among the brighter stars, Arcturus, the Plejades, &c , are referred to by Homer and still earlier writers So far as Egyptian and Chinese astronomy goes, practically the first reference to a constellation appears in Egypt with reference to the equinox which happened 3285 years BC, and in China with reference to the Pleiades in the equinox of 2357 B.C.

In observing stars nowadays, we use a transit circle which is carried round by the earth so as to pick up the stars in different circles round the axis of the earth prolonged, and by altering the inclination of the telescope of this instrument we can first get a circle of one declination

and then a circle of another

The Egyptians did not usually employ mendian observations. Did the Egyptians make star maps? They certainly
did In the temple of Denderah, which is a comparatively modern temple, there is a very precious series of records which is certainly not at all modern. It represents a good many of the Egyptian constellations. The central part was in all probability the zenith point of Denderah itself, and at a certain distance from the centre point we have the zodiac represented excentrically. constellations round the edge are those nearest the horizon; the central ones are those nearest the north pole; instead of having the Great Bear, we have the constellation of the Thigh, representing the well-known seven stars; in addition we have the constellation Hippopotamus, which has now entirely disappeared. There is also a Babylonian zodiac, which will show you that, although Babylonia and Egypt were adjacent countries, yet that they had a perfectly different set of constellations. Our present constellations came not from Egyptian times, but from much later—from Greek times. It is almost impossible to hope to recover the names of the

constellations used by people earlier than the Greeks, but still much is to be hoped from the study of the Babylonian records In these we have a snall being drawn along by the tail of a snake or dragon. It is quite possible that we may have there the origin of our constellation Draco, which is the northern constellation, and it is quite possible that this snail may indicate that the stars in it moved with very great slowness. But it is impossible at present to co-ordinate these different fancies together

A very important paper has recently been published by Mr. Le Page Renouf suggesting that before the year 1500 B.C. the Egyptians really had an idea of meridional observations. These observations are recorded in several manuscripts found in tombs; they seem to have been given as a sort of charm to the people who were buried in order to enable them to get through the difficulties of

the way in the nether world

The hieroglyphs state that a particular star of a particular Egyptian constellation is seen at a particular hour of the night, we have twelve lines representing the twelve hours of the night, and it is stated that we have in these vertical lines the equivalent of the lines in our transit "over the right eye," "over the life shoulder," or "over the left ear," as the case may be, is simply a reference to the position of the star

If this should be confirmed, one of the remarkable things about the inquiry will be that the Egyptians did not hesitate to make a constellation cover very nearly oo In those days evidently they wished to have as few constellations including as many stars as possible, in order

perhaps that things might be more easily remembered
When the zodiac of Denderah was mentioned. I pointed out the constellation of the Hippopotamus very near the north pole. This constellation is referred to in the records

in question

Such then are some of the ideas which are suggested by the recent work of the Fgyptologists You see, I trust, that it is important that this work should be continued as closely associated as possible with astronomical ideas, because, merely taking a very small part of the area of which they have begun the consideration, we have come to the conclusion that, dealing with the temples alone, there seems a very high probability that 3000, and possibly 4000 BC the Egyptians had among them men with some knowledge of astronomy, and that 6000 years ago the course of the sun through the year was practically very well known, and methods had been invented by means of which it might in time be better known, and that not very long after that they not only considered questions relating to the sun, but began to take up other questions relating to the positions and the movements of the stars. It is quite probable that 1500 years B.C. at least they had an idea of meridional observations If this be so, and if more and more can be proved, I think you will agree that, as I said before, astronomy will have a slight opportunity of repaying some of the great debt which she owes to the other sciences

I NORMAN LOCKYER

THE LATER LARVAL DEVELOPMENT OF AMPHIOXUS

THE memoir by Mr. Arthur Willey, B Sc , of University College, London, on this subject, in the Quart fours. Microsc Science, March 1891, deserves more than a passing notice. It is one of the most important contributions which have been made to a knowledge of this very interesting animal In the summer of 1889, Mr Willey was sent by Prof Ray Lankester with the aid of a Government grant to collect the larvæ and embryos of Amphioxus at Faro, near Messina He returned with a large series, and in the winter 1889-90 worke I out in the laboratory of

University College, chiefly by means of sections, the history of the formation of the atrial cavity in this animal. In a paper published jointly by Prof. Lankester and Mr. Willey (Quart. Journ Micr Sa, August 1890), it was shown that the atrial cavity does not form, as supposed by Kowalewsky and by Rolph, as the result of a down-growth of lateral epipleura, but that it forms as a longitudinal groove which sinks inwards along the ventral surface, becoming floored in by a small horizontal growth on each side corresponding merely to that portion of the adult animal's ventral surface which lies between the two metapleura. The groove, now become a narrow tube, expands right and left, until it acquires the proportions of the adult atrial chamber

The preserved material brought home by Mr. Willey in 1889 did not enable the observers to determine the mode of origin of the second row of gill-slits Stages were noted in which there were as many as fourteen gill-slits of the first series (which are placed anteriorly on the animal's right side), and stages were observed, of no greater size, in which two rows of gill-slits were presentone series on the right side and one on the left side of the pharynx, whilst the mouth, which in the specimens with a single series was completely lateral (on the left side),

had now taken up a median position

Mr. Willey again visited Faro in the summer of 1890, for the purpose of determining, by the study of living transparent larva, exactly the mode of origin of the second row of slits, and the steps in the "symmetrization" of the The brief account and few unconvincing figures given by Kowalewsky, in 1866, in relation to this matter had not commanded general confidence, although it was not hat so accurate and accomplished an observer could not have been completely mistaken. Balfour had said, in reference to Kowalewsky's observations on this matter,

that he was "tempted to suppose that his observations were made on pathological specimens"

Mr Willey completely and most successfully accomplished the object which he set before himself in his second visit to Faio, and the results obtained are given in the paper under notice, illustrated by three folding-plates He confirmed the main feature of Kowalewsky's observations, viz that the first row of gill-slits, after having (so far as the first eight are concerned) taken up a position on the right side of the pharynx, rotate downwards across the median ventral line, and rise up into position on the left side, whilst, simultaneously, a new series appears on the right side, not one by one, but as many as six being formed at approximately the same moment Mr Willey corrects Kowalewsky's brief ac count in one or two numerical details, and adds some very important facts, which are quite new. He shows. (a) that the anteriormost slit of the primary series closes up and disappears during the process of rotation; (b) that some of the hinder slits of this series, which are not far advanced when the rotation begins (there being usually fourteen, of which the last six are very small, and lie in the median ventral line), also close up, so that, when the rotation is complete, and the second series of gill-slits has advanced in development to the number of eight, a "critical phase" is reached in which there are only eight gill slits on each side of the pharynx, all fairly well developed From this time forward new gill-slits are formed on each side behind the last formed, and continue to increase in number so long as growth continues, which appears to be as long as the Amphioxus lives

But the most important discovery made by Mr. Willey is as to the origin of the endostyle, a structure which has great importance from the fact that it can be clearly identified, on account of its minute histological structure, with the endostyle of the Ascidians.

In the anterior region of the buccal cavity, previous observers have described in very young Amphioxus larvæ (with only one gill-shi) an elongated gland; "the clubshaped gland." It opens to the exterior on the left side, just in front of the by laterally-placed mouth, whence it can be traced, bending down across the median line and passing up a regist angle is the long axis of the body along the deep surface of the right wall of the buccal into the local carry. It is earliest appearance (as described by Hatschiel) resembles that of a gill-slit, though it precedes both the mouth and the first gill slit in date Mr. Willey suggests that it is a modined gill-slit. By the said of this chulls shaped glan band like trace of modified

but the <-shaped epithelial tract does not; it grows rapidly at its angle along the line or interspace between the two series of slits, forming a double tract of modified epithelium consisting of parallel extensions of the two limbs of the <- It is now the epithelium of the hypolimbs of the <- It is now the epithelium of the hypo-

202

epithenum consisting or parallel extensions of the two inthis of the 4.7. It is now the epithelium of the hypopharynged indge or endotyle pharynged indge or endotyle specially the first shaped gland so intimately associated with the first shapes of the endotyle as a modified gli-slit belonging to the secondary (the permanent right-side series). Its early development in front of the mouth indicates this, since, when the mouth acquires a modal no postion (lassing front the left towards

intra-buccal eputhelium. When there are about eight gill-slits of the primary series present, it is noticeable that the apex of the club-shaped gland is bent over, so that the gland teads to become -shaped, with the angle effects of the club-shaped gland is bent over, so that of the club-shaped gland to be the club-shaped gland to be proper limb of the
- It is a good det is smaller than the lower, but as the primary series of gill-slits move from the right side of the praym; to the left, the two humbs of the
- Secondary series of gill-slits move from the right side of the between the primary and the new secondary series of sits. The club-shaped gland-tube now arophies entirely,

the right by a relative growth, the reverse of that which brings the primary gill slits from the right to the left ly, structures just in front of it would be thrown round to the right side, the side of the secondary series of silts. He suggests that it is the early-developed auterior member of the secondary series of gill-sits; and points out that just as this modified gill-slit atrophies, so does its pair in

the primary series, viz. the first.

Mr. Willey points out the possible importance of these facts in reference to the views of Dohrn and of Van Beneden, and makes an interesting comparison between the Ascidian tadpole and the Amphioxus larva, with a

view to suggesting some explanation of the extraordinary asymmetry of the latter. Mr. Willey thinks that a cause of the one sided position of the mouth and of the primary series of gill-slits in the Amphioxus larva may be found in the excessive anterior prolongation of the notochord at an early period of development, necessitating a pushing to either one side or the other of the mouth There appears to be nothing in the mode of life of the larvaa free-swimming ciliated creature-which can be correlated with its asymmetry. The gradual process of "symmetrization," by which the Amphioxus establishes more or less completely a bilateral symmetry on its way to the adult form, is exactly the converse of that process by which the symmetrical larva of the Pleuronectid fishes becomes one-sided, but in the latter case the asymmetry is clearly correlated with a peculiar life on the sea bottom, whilst in the former case we can discover no such relation to environment.

THE CARDIFF MEETING OF THE BRITISH ASSUCIATION

To arrange for the reception of the members of the British Association who will visit Cardiff in August next, an influential Local Committee has been formed. with the Most Honourable the Marquis of Bute, K.T., Mayor of Cardiff, as Chairman, and a substantial sum has been subscribed for the purpose of defraying the cost of the meeting.

Several sub committees have been formed, all of which report to the Executive Committee, to which also the Council of the British Association has assigned the duty of electing new members and associates Up to the pre-sent time 7 life members have been added, and over 200 annual members and associates, and as the time for the meeting approaches the number of new members and associates will be largely increased

It may be convenient to describe what has been done by the sub-committees, so as to give a systematic account of the preparations already made and in progress to provide for the comfort and entertainment of our expected

visitors

(1) Hospitality and Lodgings — Many of the principal residents in Cardiff and the neighbourhood have signified to the Committee their desire to entertain members of the Association, and as the date of the meeting draws nearer numerous additional offers will be made by those of the townsmen who are unwilling or unable to fix their en-gagements so long beforehand It is understood that those ladies and gentlemen who have offered to invite guests will send out invitations as soon as it is known to the Committee who are coming.

The hotel and lodging accommodation is not so great as in some other towns, but the Committee feel sure that with the private hospitality which will be offered there will be enough for the needs of our visitors. The list will be enough for the needs of our visitors. The list of hotels and lodgings will be ready for distribution about the middle of July, it having been delayed to make the list as complete as possible. The list will be accompanied by a map of Cardiff taken from the most recently

executed ones.

(2) Reception and Section Rooms - The reception room will be at the Town Hall, practically the whole of which has been placed at the disposal of the Local Committee for the use of the Association The vestibule will be devoted to the sale of tickets, the distribution of pro rammes, and other information, whilst the Assembly Rooms will be fitted up as a drawing-room with writing-tables, post-office facilities, and a book-stall The Council, Committee of Recommendations, and General Committee will meet in various rooms, and others will be set apart for the officers of the Association.

As the Town Hall is about half a mile from the Section room furthest away, a portion of the Drill Hall, the use of which has been kindly granted by Lord Bute, Colonel Gaskell, and Colonel Page, will be fitted up as a drawingroom, and the remainder will be used as a luncheon-room. As the Drill Hall is situated within very easy distance of almost all the Section rooms, the members of the Association will doubtless appreciate the advantage of having a drawing-room and dining-room so close at hand.

The majority of the Section rooms are very close to-gether, and the greatest distance is not more than half a between the extreme points, so that even that distance should offer no difficulty in the way of members wishing to attend different Sections

(3) Entertainments,-The usual conversazioni will be given on Thursday, August 20, and on Tuesday, the 25th, and it is hoped that scientific men will aid the Committee in contributing towards the entertainment of our guests by the exhibition of novel experiments or specimens. The Park Hall, in which the conversations will be held, is well suited to this purpose, and it is the desire of the Committee to introduce as many scientific novelties as possible

A garden party, to which all members of the Association will be invited, will be given by Lord and Lady Bute, probably on the Friday afternoon, though the date may be subject to alteration. Other social entertainments Other social entertainments are projected by Lord Windsor and others, and Cardiff will probably in this respect not fall behind what the members have been accustomed to at other places of

meeting.

(4) Encursions —A considerable variety of excursions has been provided for both the Saturday and the following Thursday For the former, arrangements are being made by Sir W T Lewis for a party of members to visit the Cardiff Docks, by a committee appointed by the Board of Directors to visit the Barry Docks, by the Mayor of Newport and the Chamber of Commerce for a party to visit Newport and Caerleon A special excursion is being arranged by the Colonel commanding the Severn Valley division of submarine miners for officers of the British Army to inspect the Severn Valley defences. The Army to inspect the Severi vary account of the steep and flat holmes, and will continue with the civilians on board to Weston, from which they will visit Worlebury Hill and camp.

Other excursions will be of geological and archæological interest, and will include excursions to Penarth and Lavernock, where the finest section of Rhatic beds in England is exposed; to the interesting dolmens at St. Nicholas and St Lythan's; to Llantwit-major, where a year or two ago the remains of a Roman villa were unearthed, and where a college is said to have existed in the fourth century, to Tintern Abbey and Ragian Castle, the Forest of Dean, Merthyr, Brecon, and to some of the numerous collieries and iron works in the South Wales coal-field A practical natural history excursion is being organized by the Cardiff Naturalists' Society to the Vale of Neath, which from the beauty of the spot should prove attractive Several owners of works in the neighbourhood of Cardiff have expressed their willingness to throw them open to the members, and arrangements will be made for visits to some of them.

(5) Publications —A guide-book to Cardiff is being prepared for distribution to all members and associates, and the descriptive articles have been intrusted to the gentiemen who were best fitted to write inem. The article on the history and whilst that on the topography of Cardiff was undertaken by the late James A. Corbett, who, unfortunately, died before it was quite complete. Mr. T Forster Brown, President of Section G, has undertaken the description of the mining, geological, and statistical features of the district; the industrial portion being in the bands of Mr.

Gallowsy. The geological, soological, and botanical descriptions have been written by Mr. T. H. Thomas and Prof. W. N. Parker, with the help of many others. The account of the educational arrangements of Cardiff will be treated of by Mr. Whitmell, Inspector of Schools, and Principal J. V. Jones

The excursions hand-book will contain a map, on a scale of four miles to the inch, of the whole of the district in which the excursions will be held, specially prepared for the Committee by Messrs. Bartholomew and Co, Edinburgh. As detailed accounts as possible of the various points to be seen in the excursions will be given the guide-book, it is thought that a very complete description of everything connected with this portion of South

Wales will be farmished to the visitors. Other Committees have been formed for the evening lectures and the working men's lecture, but little more can be said shout them than that they will provide to the fullest extent for the wants of the Association. The Local Committee are amount shat this shall be the case in every particular, so that the first visit to the metropy particular, so that the first visit to the metropy meetings of the Association.

R. W. ATRISTON

MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM

WE have received the annual report of the Council of this Association, presented at the general meeting on June 24—the President, Frof Ray Lankester, F.R.S., in the chair. In the sea, as well as on land, the severe winter appears to have had a marked effect on the fauna, and there is also a complaint of mortality in the aquarum attached to the Laboratory during the colder months, are result perhaps somewhat unexpected, conndering the comparatively high reference temperature of the sea to the comparative of the properties of the sea of the comparative of the sea of the sea of the sea of the comparative of the sea of the

Under the head of the library (which ought to be represented in the balance-sheet by a larger sum than is at present debited to ii) the Association is to be congratulated on having received the gift of the late Mr Spence Bate's library, constituting an exceedingly valuable collection of the literature of Crustacca.

Some of the changes made in the permanent staff have been chronicled already Mr. Calderwood has replaced Mr. Bourne as Director, and has appointed Mr. H. Dickson to succeed Mr. Gorstang, who took up a Fellowship at the Owens College in December last. Two employing members have been added to the staff. Two employing members have been added to the staff, and the staff of the staff

Eleven gentlemen have visited the Laboratory during the year for the purposes of research, some of them on more than one occasion This number, however, is by no means as large as it should be.

The balance-sheet shows a satisfactory, if small, increase in receipts, the items pointing to an increased use

of the Laboratory, both for research and for the purchase of material for teaching purposes. A sum of £500 (in addition to the annual grant of £500) has been placed on the Civil Service estimates for the current year, which will, if passed, place the Association in a position to carry on its work with less difficulty than has hitherto been the case

UNIVERSITY EXTENSION STUDENTS AT

THE work done by University Extension students at Cambridge last year was so satisfactory that the Syndicate for local lectures are encouraged to repeat the experiment this year. They will be prepared to receive a larger number of students, say from 60 to 80, most of whom will be lodged either at Selwyn College or at Newnham College. The period of study will last from July 28 to August 22, or nearly a month in all byndicate have just issued a detailed programme of the various courses of study, and we are glad to see that due attention has been paid to the claims of science as well as to those of literature and art. At the chemical laboratory, on alternate days, there will be a course of demonstrations illustrating the methods of chemical manipulation in a short series of typical experiments. The pupils will be first shown each experiment, and will then be expected to repeat it for themselves. At the then be expected to repeat it for inemselves. At the Cavendish Laboratory, on alternate days, a course of short experimental lectures, chiefly on electricity and magnetism, will be delivered, and most of the experi-ments shown in the lectures will afterwards be performed by the students for themselves Geology will be studied, on alternate days, at the Woodwardian Museum, where on alternate days, at the woodwaldian muscul, there will be a course of demonstrations on the leading fossil types of the animal kingdom, from the specimens in the Museum A course of demonstrations, followed by practical work, will be given, on alternate days, in the physiological laboratory, and Mr Graham, chief assistant at the Observatory, will receive students and explain the as the Observatory, win receive students and explant the uses of astronomical instruments. Afrangements will also be made for taking small parties of students to the Observatory at night. Single lectures will be delivered by various eminent Cambridge men, and in this part of the work science will be represented by Prof G. H. Darwin, who will lecture on the history of the moon or some allied subject. We may note that the students in science will be allowed to read in the Philosophical Library.

NORMAN R. POGSON, CI.E.

WE regret to have to announce the death of Mir Norman Pogson, for thrity years the Director of the Observatory at Madras Mr Pogson has been so long absent from England that, in a sense, he may be said to have outlived his reputation, but those who can recall the condition of astronomy in this country some thirty years since will remember him as a rising astronomer of considerable promise, and as one of the most indefangable observers at that time. If his subsequent career has not entirely fulfilled his early promise, perhaps the condition of the Madras Observatory is to some ment is very old and inadequate, and possibly Mr Pogson has accomplished all that could be done with his instruments and his staff.

ments and his staff.

Mr Pogson's astronomical career commenced at Mr Bishop's Observatory in Regent's Park, at that time under the direction of Mr J R. Hind, and he there took part in the observations for forming the ecliptic chairs published from that Observatory. In 1851 he left London

to assume an assistantship in the Radcliffe Observatory, Oxford, under the late Mr. Johnson; and there his zeal was rewarded by the discovery of several minor planets, in days when the number of the known asteroids was comparatively small, and their discovery conferred some little distinction upon their fortunate discoverer. Of greater importance to astronomy was his subsequent devotion to variable stars and photometry, the latter carried out, we believe, with the apparently inappropriate instrumental means of the heliometer of the Radcliffe Observatory. Oxford. But the result of his investigation of the amount of light that separates two consecutive magnitudes has never been displaced, and the fortunate employment of the number, whose logarithm is 04, to express this ratio will probably long connect Mr Pogson's name with the history of accurate photometry.

After a somewhat short stay at the Hartwell Observa-Mr Pogson left England in 1861 to take charge of the Madras Observatory. His direction of that institu-tion will always be remembered in connection with the extraordinary discovery of a telescopic comet, effected in consequence of the telegraphic communication he received from Prof Klinkerfues, who expected that Biela's comet might be seen in the constellation Centaur, after the brilliant meteoric shower to which that comet had given rise in November 1872 Mr Pogson looked in the direction indicated, and by a remarkable coincidence found a comet, which he observed on two, and only two, occasions The orbit remains, therefore, indeterminate, but there is good reason to believe that the object seen was in no way connected with either of the two condensations which together make up the lost comet of Biela And thus another and not uninteresting chapter was added to the history of this comet Several volumes of observations have been published under Mr Pogson's direction, the last bears the date of 1870, so that probably, and as the Director has often lamented, the reductions are considerably in arrear

It will be interesting to watch the future of this Observatory It is to be hoped that some steps will be taken to place it more in accordance with the requirements of the present time. We believe that its abandonment has even been canvassed, but it cannot be sufficiently regretted if an Observatory, possessing as that does many historical associations, and occupying a very favourable position on the earth's surface, be allowed to disappear. W. E. P.

NOTES.

THE death of Wilhelm Weber, the illustrious physicist, is announced He died at Gottingen on June 23 On a future occasion we shall give some account of his services to science.

THE second lecture in connection with the Faraday Centenary was delivered by Prof Dewar, F R S, at the Royal Institution on Friday evening last.

On Tuesday, Lord Cranbrook, in the House of Lords, moved the second reading of a Bill the object of which is to allow the managers of science and art schools to transfer them to local authorities when they desire to do so. Lord Cranbrook explained that at present there were considerable difficulties in the way, and that the process was a very long and tedious one. The Bill proposed to make these schools transferable in the same way as ordinary schools could be transferred to School Boards. The Bill was read a second time.

DRS. J. BORNMÜLLER AND P. SINTENIS propose to occupy the present summer with an investigation of the flora of the islands Samothrace and Thasos, from which very few collections are to be found in European herbaria, also of Mount Athos

and of the Bithynian Olympus, They then intend to take up their winter quarters in Mossul, and to spend the following spring and early summer in the comparatively unknown mountainous region of Diebel Hamzin near Bagdad, and the mountains to the north and east of Mossul.

THE distinguished Italian botanist, Prof O. Penzig, is about to start on a botanical expedition to Massowah and Bogos.

MR I T NICOLSON, at present Prof. Ewing's demonstrator in the University of Cambridge, has been appointed to the Chair of Mechanical Engineering in the McGill University. Montreal

A STALL for the sale of "zoological photographs" has just been opened in the Zoological Society's Gardens. It is placed in the centre of the Gardens, near the band-stand, and has an attractive exterior The photographs sold are mostly representations of animals in the Society's Gardens, but also include some taken in the Jardin d'Acclimatation of Paris, and in other similar establishments.

THE marine laboratory of the Johns Hopkins University will be open this summer at Port Antonio on the north-east coast of Jamaica According to Science of June 10. Prof. Brooks and some members of his party had already started for the station.

THERE has been lately formed in Berlin (we learn from Natur w. Rasch) a "Union of frieads of Astronomy and Cosmical Physics," with the view of organizing practical co operation in these subjects of research in Germany, Austria, Hungary, Switzerland, and neighbouring countries, and also in the colonies, and where membership may be desired. The object is to be sought by means of free communications of the members or groups of members to head quarters, whence advice and results of observations, &c , will be i-saed, Sections are formed for observations (1) of the sun , (2) of the moon , (3) of the intensity and colour of starlight and of the Milky Way , (4) of the rodiacal light and meteors , (5) of polar light, terrestrial magnetism, earth currents, and atmospheric electricity, and (6) of clouds, halos, and thunderstorms. Prof Lehman Filhes has been elected President of the Union, and the presidents of the sections are Forster, M W Meyer, Plassmann, Jesse, Weinstein, and Reimann.

ACCORDING to a telegram sent through Reuter's Agency from San Francisco on June 29, a series of sudden sharp earthquake shocks, accompanied by subterranean rumblings, passed through San José, California, that morning The first shock was so violent that the electric-light tower, two hundred and forty feet high, swayed for at least ten feet. A panic prevailed in the town, and in two of the principal hotels, which were filled with tourists from the East, men and women rushed half dressed from their rooms into the corridors in a great state of alarm. The city rocked like a ship in the trough of the sca, and when the second shock occurred, buildings rose and fell with a slow uadulating motion, one partly erected brick building tumbling to the ground Many chimneys fell, and a large number of wiadows were broken, while considerable damage was done to crockery and other fragile articles in the houses

GERMANY had very heavy rains on November 22 to 24 last year, causing floods at a rather unusual time in the region of the Elbe, Weser, &c It is shown by Prof. Hellmann, that Middle and West Germany were then on the front side of a deep depression, which passed very slowly from north to south, taking about 90 hours from the North Sea to Central Germany, less than half the usual speed from west to east. A region of high pressure with cold lay to the east, blocking the course in that direction, and this afterwards spread over the flooded country, covering it with ice.

THE Central Mcteorological Observatory at Tokio, Japan. has begun the publication of hourly meteorological observations. commencing with January 1890 The observations are contained in monthly Bulletins, and include all the usual elements, together with vapour tension, humidity, earth temperature, bright sunshine, and hourly and daily means Meteorological observations have been made for some years in various parts of Japan, including hourly observations at Tokio since January 1, 1886, but have hitherto only been published for certain hours. The observations are all made without selfrecording instruments, excepting those of wind and sunshine Some years ago the Director of the Service, I. Arai, visited this country, and other European countries, for the purpose of studying the various meteorological organizations, and we have no doubt that this important publication will be very valuable for meteorological researches referring to the North Pacific Ocean, where information is comparatively scanty

M. MASPERO has an interesting article in the current number of La Nature on the dog in ancient Egypt It is illustrated by representations of dogs reproduced from Egyptian monuments. and by a mummy of a dog recently opened and sketched by M Beckmann. In ancient Egypt, as in modern Europe, the dog was regarded both as a friend and as a useful servant. He also received the honours of a god, and there are cemeteries of does (corresponding to the cemeteries of cats) where minimies have been found by the thousand Attempts have been made to identify the various species of dogs represented in wall paintings, but those naturalists who have investigated the subject have not always arrived at the same conclusions. M Maspero points out that mummies supply more trustworthy materials for study, and urges that men of science should lose no time in examitting some of them, as cemeteries of animals are being very rapidly "exploited"

A COMMERCIAL company has for some time been working quarters in the neighbourhood of the well knowing jaleaul grooves at Kelley Island, Ohio, and it was feared that these remarkable relies of the glacial epoch might be wholly destroyed Fortunately the president of the company understands the interest of the phenomens, and has taken care to prevent the most artiking of them from being injured. We learn from the Grevanda Leader that some of the grooves have now been readered aste, the company at its recent annual meeting having decided that the crocks on which they are farrowed should be made over to the presented in the presented over the three distributions, and the state of the company of the presented in the presented over the presented in the presented over the three first of the presented in the presented over the presented in the presented over the three first of sections.

MR C DAVIES SHERBORN IS, we are glad to find, making satisfactory progress with the stupendous task he has undertaken in the production of his "Index Generum et Specierum Animalium" Mr Sherborn has found it absolutely necessary to accept the year 1758, the date of the tenth edition of Linneus's "Systema," instead of the twelfth edition (1766), as the startingpoint of binomial nomenclature in zoology, and this decision was greatly strengthened by the advice of Prof Sven Loven. Dr D Sharp, and others who had carefully studied the question. This is the only alteration which has been made in the original scheme (see NATURE, vol xln. p 54) During the year, five hundred volumes have been worked through, page by page, and a total of forty thousand species have been recorded, are duplicate, involving a use of 80,000 slips Each species is recorded on a separate slip (5 inches x 21), the whole of the reference, with the sole exception of the page, being printed with india-rubber type, thus insuring perfect accuracy of date and parts of volumes: as the pages are also checked during work, the chances of misquotation are reduced to a minimum. As the volumes mentioned include the whole of the publications of Linnieus, many of Fabricius, Thunberg, and other voluminous authors of that early period, it is, perhaps, permissible to think that more rapid progress may be made in future years. The dates of publication of the separate parts of a work have been carefully attended to, and much value ble information has been obtained. Some of this has appeared in the Annals of Natural History (Pallas's "Icones Insect ." "Nov Spec Quad.," and While's " [ournal"], while much remains in manuscript until the final completion of detail admits of its publication. As is well known, the authorities of the Natural History Museum have rendered every facility to Mr. Sherborn for the prosecution of his work, and the storage of the manuscripts within the walls of that institution, reducing the risk of loss by fire to a minimum, is a concession highly valued by the author. One set of the slips is arranged in order of genera, and, on application, is available for reference to anyone compiling a monograph of a genus The manuscript is frequently consulted by those working at the Natural History Museum, even in its present imperfect state, and will, from the very nature of the method of recording, prove of increasing value as it grows to larger proportions

In the report of the trautees of the South African Museum for Bogo it is stated that the curstor, Mr. R. Trimen, has completed a thorough rearrangement of the fine collection of South African Durrial Lepdopters in accordance with the monograph of those meets recently published by him, incorporating many additional species, and replacing imperfect or wore examples by freiller and more characteristic specimens. He has also begun the rearrangement of the more numerous and less known Crepta cular and Nocturnal Lepdoptera. Mr. Trimen has completed for publication two papers—one on the very interesting series for publication two papers.—one on the very interesting series were considered to the series of the serie

An interesting account of the nest and eggs of the cat bird (.leluradus verides, Latham) is given by Mr A J North in the latest number of the Records of the Australian Museum (vol 1. No 6) The habitat of the cat bird is the dense scrubs of the constal ranges of New South Wales Although the bird is common, authentic specimens of its nest and eggs seem to have been unknown until lately For an opportunity of examining such specimens, Mr. North is indebted to Mr W. J Grimes, an enthusiastic cologist, who recently secured two nests of this species on the Tweed River The nest is a beautiful structure, being bowl shaped, and composed exteriorly of long twigs, entwined around the large broad leaves of Ptarietia argyrodendron, and other broad leaved trees, some of the leaves measuring eleven inches in length by four inches in breadth. The leaves appear to have been picked when green, so beautifully do they fit the rounded form of the nest, one side of which is almost hidden by them The interior of the nest is lined entirely with fine twies. The eggs are two in number for a sitting, oval in form, being but slightly compressed at the smaller end, of a uniform creamy white very faintly tinged with green, the shell being comparatively smooth and slightly glossy. Although the cat bird is usually included in the family of bower-building birds, Mr North has never known or heard of its constructing a hower

A CATALOGUE of the Australian birds in the Australian Museum, at Sydney, by Dr. E. P. Ramsay, is being published. Part III., which has just been issued, deals with Paittaci.

As a substance peculiarly fitted, by reason of its high dispersive power, and transparency for ultra-violet rays, for study of theultra-violet part of the spectrum, Herr Wolter has recently recommended, in a Hamburg serial, a-monobiomanchtalin With a prism of the liquid, he could trace the spectrum beyond N on a fluorescein-solution. Besides the above named properties, the substance has for boiling-point 277° C; it has an offensive smell like carbon sulphide, and its index of refraction varies much less with temperature than in the case of that bound

THE material resources of the southern part of Maryland are sill so ungerficitly known that a scennific expedition for the investigation of the district was recently organized. The expedition was formed under the joint asspaces of the Johns Hopkins University, the Maryland Agricultural College, and he U.S. Geological Survey. An interesting report of the work done has been published in one of the Johns Hopkins University Circulars.

DA ALPRED TUCKERMAN has compiled an excellent "Bibliography of the Chemosal Inflaence of Light," which has been published as one of the Smithsonian miscellaneous collections. As the compiler had in verw only the scientific aspects of the subject, he has omitted nearly all the practical applications, including that of photography. An index to the intensive of photography is being prepared under the majnees of the common of the Alvancement of Science.

Tits College of Scence, Imperial University, Japan, has susued the first part of the fourth volume of its Journal. It opens with a paper on the fetal membranes of Chelonia, by K. Mitsakuri After this come the following articles—On the development of Aranena, by Kamakichi Kahinonye, observations on frish-water Polyzon, by A. Oka, on Different sufferium, n. sp., by Seitaro Goto, a new species of Hymenomycetone Fungus injurious to the mulberty tree, by Nobajiro Tanaka; notes on the irritability of the saigma, by M. Myroshi, notes on the development of the suppraesal boddes in the mouse, by Masaniro Inaka. Each of the papers at allustrated.

MR. C. C. VRVERS, Leeds, has sent us a copy of the fourth edition, illustrated, of his "Practical Amateur Photography" The volume is described in the preface as "a simple text book for the beginner, and a handy work of reference for the advanced photographer " Mr Vevers has also published an illustrated catalogue of photographic appraisus.

THE Manchester Microscopical Society has issued its Transactions and Annual Report, 1890 The volume includes two Presidential addresses by Prof Milnes Marshall, papers and communications read by the members, and a last of members

We have received from Mr William F Clay, Edinburgh, a catalogue of scientific books which he offers for sale. The works relate to chemistry and allied sciences

As briefly announced in our report of the last meeting of the Paris Academy of Sciences a new compound of iron and carbon monoxide has been obtained by M. Berthelot, analogous to the nickel compound described last year by Messra Mond. Lang. and Quincke In order to obtain it, the iron requires to be in a very finely divided state, and free from admixed oxide. It is most suitably obtained by reducing dried precipitated ferric oxide or oxide obtained by ignition of ferrous oxalate in a current of pure hydrogen. When carbon moaoxide is led over metallic iron thus prepared, and the tube containing it gently warmed to about 45° C., the reaction commences, and if the issuing gas, after being washed through water, is ignited at a jet, the flame is observed to be quite different from that of pure carbon monoxide, being brilliantly luminous, almost white, and emitting rays which furnish a definite spectrum. Moreover, if a cold porcelain tile or evaporating basin is depressed upon the flame a deposit of metallic iron more or less admixed with oxide is obtained.

indicating the existence in the issuing gas of the vapour of a ferruginous compound. A drop of dilute hydrochloric acid at once dissolves the stain, and the solution affords the ordinary reactions of 1ron, yielding Prussian blue with potassium ferrocyanide for instance. When the gases are passed through a strictured tube, such as is employed in Marsh's arsenic apparatusa portion of which is heated to redness, an annular deposit of metallic iron is obtained, containing a slight amount of admixed carbon. M Berthelot has not yet succeeded in obtaining sufficient of the new compound to condense it to the liquid form, but further experiments with that end in view are in progress. The formation of this volatile compound of iron and carbon monoxide will undoubtedly prove of great interest from a metallurgical point of view, as it may assist in elucidating several of the as yet little understood furnace reactions. M. Berthelot further expresses the opinion that it may help to explain the formation of bubble flaws in manufactured from which have so frequently led to such unfortunate re-ults. In addition to the preparation of Iron carbonyl, M. Berthelot describes several new reactions of nickel carbonyl. It will be remembered that this substance is a liquid boiling at 46°, so volatile that, according to M. Berthelot, its vapour tension at 16° is a quarter of an atmosphere A drop placed upon a glass plate rapidly volatilizes, the portion last to disappear being for a few moments cooled down by the evaporation of the first portion to such an extent as to form beautiful little crystals When suddenly heated to 70° it detonates, the detonating reaction being expressed by the countion Ni(CO), = 2CO, + 2C + Ni When mixed with oxygen, simple agitation of the tube containing it over increury brings about detonation. When oxygen is permitted to slowly gain access to the liquid oxide, a solid substance is formed, which is green if the oxygen is moist and brownish-yellow if dry. In contact with oil of vitriol the liquid compound appears to be unaffected for a few moments, but suddenly explodes with production of flame Nitric oxide reacts in a most beautiful manner. either when passed into the liquid or its vapour, bright blue fumes being produced of a complex compound, which eventually anbside, forming a blue solid These blue vapours completely fill the whole vessel, and their formation affords one of the prettiest experiments yet described

CONTEMPORANKOUSLY with the above work of M. Berthelot, Mr. Mond and his co-workers have also been conducting experiments with the view to the preparation of iron carbonyl, which have been so successful that a brief account of them was laid before the Chemical Society at their last meeting. Further particulars of these experiments will be given as soon as published.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (Macacus rhesus 9) from India, presented by Mr Albert Job, an American Red Fox (Canis fulvus) from North America, presented by Mr W. Reading, a Two-spotted Paradoxure (Nandinia binotata) from West Africa, presented by Mr E. G. Parkinson, a Sinaitle Ibex (Capra sinastic) from Palestine, presented by Sir James Anderson , two Gaimard's Rat-Kangaroos (Hypsiprymnus gaimards) from Australia, presented by Mr. Walter Howker, a Cuckoo (Cuculus canorus), British, presented by Mr. Stacy Marks, R A., F Z S , two Red-billed Tree Ducks (Dendrocygna autumnalis) from America, presented by Mr. Keswick; two White-faced Tree Ducks (Dendrocvena viduata) from Brazil. presented by Captain C A. Findlay, R.N R.; a Common Viper (Vipera berus), British, presented by Mr. J. Sargeant; two White-headed Sea-Eagles (Haliactus leucocephalus) from North America, deposited, a Burchell's Zebra (Equus burchelli &), a Derbian Wallaby (Halmaturus der bianus), three Common Night Herons (Nucticorax priseus), bred in the Gardens.

OUR ASTRONOMICAL COLUMN

THE CAPILIER THEORY OF COMETS.-The last three numbers of the Bulletin Attronomique (April-June) have contained papers by M. L. Schulliof, "Sur les Grandes Perturbations des Comètes by M. L. Schulloi, "Sur les Grandes Perturbations des Comètes Périodiques," which place beyond doubt the idea that the periodic comets of our system are captured by the perturbing action of planets. The main object of the research was to develop the relations existing between the elements of the comet's orbut the relations existing between the elements of the council young before and after its entrance within the sphere of activity of the disturbing planet. With the criteria obtained, and some results previously formulated by M Tisserand, it is possible to decide the question as to the identity of two comets of which the time of revolution of one is known, even when the comet is believed to have passed several times within Jupiter's sphere of activity between two apparitions. This result is of the highest importance, for it is only by such means that individual comets can be identified. They cannot be recognized by their appear-

ance, as they possess no peculiar characteristic that can be telescopically observed.

M. Schulhof suggests that, in the light of recent work, periodic comets should not now be classified according to their aphelior contents around not now de classifier according to their appears of detacles, but arranged in groups the mean appletion distinct of or other of the planets. Such a division has been made for comest having periods between 10 and 10,000 years. From the tabulated results, it appears that four camets have appletion distinction with the property of the planets. tances which differ but little from the application distance of Mercury. The Venus group numbers seven, the earth's group ten Mars possesses four comets, and Jupiter twenty-three Saturn has a family of nine, Uranus eight, and Neptune five

WOLF'S PERIODIC COMET (b 1891).—The following ephemeria is from one given by Frof Berberich in Edinburgh Cricular No. 17. From Astronomich Machrichten, No. 3942, it appears that Dr. Spitalier observed the comet on May 2, that is, before Frof Earnatd I he brightness on the date (May 4) of rediscovery by the latter observer has been taken as unity

The comet is now in Pisce, and in the beginning of September will pass through the Plendes. M. Bigourdan, of Paris Observatory, observed it on June 12, and remarked that it was "une nébulosité ronde, d'eaviron 20" de diamètre, de grandeur 13 3"

YORUBA AND GAZALAND.

A T the meeting of the Royal Geographical Society, on Monday, two papers were read, one by Mr. Alvan Milson, on the Yoruba country, West Africa, and the other by Mr. Denis Doyle, on a journey in Gazaland, in South-East Africa.

The ancient kingdom of Yoruba may be taken as one of the most interesting of the great tribal divisions of West Africa, between the Gold Coast and the Niger.

perween the Gota Cossa and the Niger.

Landing at Lagos, the only natural harbour on a thousand
miles of coast, a narrow entrance with a 55-feet bar leads into
the intricace chain of waterways which extends, with few and
signit mierruptions, for 500 miles from the Volka river to the
Benin branch of the Niger Delta. From the cast and west,

from the Benin river and the waters of the Dahomian frontier, the coast of the gulf is backed by intersecting channels of fresh water flowing steadily from either hand towards the Lagos outlet. In many places these narrow and brinming channels are separated from the onslaught of the Atlantic rollers by no more than hwe or six level yards of shifting sand, the spr from the ocean drifts over them, and the roar of the surf heard by the native as he glides over their calm surface in his fragile canoe. These so-called "largons of the Bight of Benin" form but a small portion of the littoral river systems of West Africa; for from Cape Palmas to Cape Three Points the long Kroo coast is lined by inland waters for the greater part of 300 miles, and beyond the rocky spurs of the beautiful Gold Coast the Dahomian shores have the same remarkable formation. At right angles to this network of channels numerous rivers flow down from the uplands of the interior, carrying in their rapid Streams vast quantities of sand and mud with which they busily build out the land At first sight it seems strange that so many and such powerful streams, flowing strongly towards the sea should suddenly be turned aside from their courses by so narrow and fragile a barrier of shifting sand Io the influence of the sheltering headlands which jut out towards the south; to the rapid Guinea current which tears away the face of their rocky shores and hurries towards the east a ceaseless stream of sand . to the simust ideless ocean, and the absence of high winds, for the strength and duration of a West African tornado are but slight as compared with the hurricanes of the West Indies or the gales of our stormy coast, and above all to the enormous growths of floating papyrus and water grass which line the breaking through into the ocean, are due the formation and con-tinual development of this strange delta system. For these rivers are in most instances choked for many inties by a floating rivers are in most instances chosen for many miles by a floating papyray-sod bound together by wild water-fig: and palm-wine palms (Azphia vini/rza), and when the floods come down from the interior great masses of this floating vegetation are torn away and carried down to the lagoons and onwards towards the sea Hundreds of acres of these grass islets are annually carried down from each of these rivers, and are driven against the banks of the lutoral lagoons, where they lodge and grow, and eventually become anchored in their places by more permanent vegetation.

In this manner the lagoon sides are padded for hundreds of in this manner the ingoon sites are pauded for nundreds of yards, and even, in some instance, for two or three miles in depth on either hand, and their banks are protected from the wash of the current and the weight of the accumulated waters, By this means the final barrier of sca-sand is strengthened, and By this means the trail parrier of sea-sana is acceptioned, and the inland waters, although they frequently rise to a height of 5 to 6 feet above the sea-level, are effectually prevented from bursting through their banks. Not only are these growths a permanent protection to the land, but by their very nature, floating as they do on the surface of the water, they rise and fall with the floods, and are always ready with their assistance at the right time and place. Were all the rivers which feed the lagoons freed from their natural obstructions, as is the case with lagoons freed from their natural obstructions, as is the case what the Ogun twer near Lagos, the interior to a distance of from thirty to seventy miles would be thrown open to commerce, and the wonderful system of inland navigation which fosters the coast traffic would be still further developed.

Mr. Millson went on to describe a journey from the coast to

MI. Milliod went on to describe a journey note to construct the literor, the country raing from terrace to terrace. He then spoke at some length of the Yoruba people and country. About eighty miles from the coast, at Oda Ona Kekere, the dense forest suddenly gives place to open cultivated land, and a densely peopled country. Some three miles to the north of Odo Ona Kekere, from the crest of a to the north of Odo Ona Keerer, from the crest of a rising in the undulating land the great city of Ibadan— the London of Negroland—comes full in view, extending for over aix miles from east to west, and for more than three from north to south. Surrounded by its farming villages, 163 in number, Ibadan counts over 200,000 soul-, while within the walls of the city itself at least 120,000 people are gathered. Its sea of brown roofs covers an area of nearly 16 square miles, and the ditches and walls of hartened clay which surround it are more than 18 miles in circumference. Its houses are built round more than 18 miles in circumstenence. Its houses are built round courtyards with a single circumser, and form in themselves no courtyards with a single circumser, and form in themselves no courty and the single circumsers and the single circumsers are made of a light covering of palm leaves and grass in order to avoid the danger of extensive configurations. In the winding tocky attents which interacts these large compounds in every

direction, are countless market booths and occasional market direction, are countless market booths and occasional market places, where the inhabitants can purchase native produce, food, and European luxuries. In the same way, by the sides of the country roads, are built at tregular intervals varying from one to six miles, long low sheds close by some well or running water, where the farm women sit and "make their market." In the farms the farm women sit and "make their market". In the farms which extend throughout the country from horison to horison as one journeys through it, save where the land is too poor, or the fear of war has desolated the neighbourhood, can be heard the crowing of cocks, the barking of dogs, the shrill laughter of children, and the vociferous clamour of native homestcad gossip. For among natives, as among seafaring folk at home, a hundred yards or so is no impediment to polite conversation. From this being naturally pitched for distant communication cannot readily be restrained or focussed for nearer ranges of social intercourse. The consequent turmoil and shrill cries are apt at first to un settle the nerves of an inexperienced traveller, but a few weeks' residence in the country not only accustoms one to their manner of speech, but inures one's system to the sudden shock of their rous voices.

Northward from Ibadan, which may be described as the Northward from Itadaa, which may be described as the centre of the chief military and commercial power in Yoruba, centre of the chief military and commercial power in Yoruba, centre of the chief with the control of t spur which leaves its traces in deep scores along the flanks of the poor animals. Far and wide the land has for generations, and indeed for centures, been cultivated by these industrious natives. The hatchet, the fire and the hoe, have removed all traces of the original forest, save indeed where a dark trail of green across the landscape shows where the valley of some narrow watercourse or larger river is hidden among trees. For two or three years at most the land is allowed to be fallow, while for three or four years double or treble crops are raised with no further cultivation than an occasional scrape with a hoe, and during its fallow time no further care is taken of it than to let a during its fallow time no further care is taken of it than to let a rank growth of reedy grass spring up some 6 or 5 feet in a rank growth of reedy grass spring up to the control of the restriction of th generations to support its owners

Mr. Doyle, who accompanies King Gungunhana's two envoys to this country, described his journey from the Mashonaland plateau down through Gazaland to the mouth of the Limpopo At first the journey was through a broken platean country, issing to 5000 feet and over, and well adapted for farming ising to 5000 feet and over, and well adapted for larming operations. After fources days' travel, the country suddenly form and the fources of the country suddenly for many miles the altitude was no more than 300 feet, and as it was the rainy season when Mr. Doyle and his companions passed through, they found the country almost entirely a swamp. The actual distance travelled was between 700 and 800 miles, which was traversed in forty-six days

THE CONDITION OF SPACE

THE question of the condition of inter-planetary space, with special reference to the possibility that it offers a resistance to the passage of the heavenly bodies, has for long occupied the attention of astronomers, but is even yet far from receiving a satisfactory or definite solution. Three hypotheses seem to be

a satisfactory or dennite soution. I arrie nypotnesse seem to ue more or less in vogne.—

(i) That it is filled with "ether," differing entirely in its properties from ordinary matter, and offering no resistance to the passage of solid or gaseous bodies. Radiant energy as transmitted by the vibiatory motion of the ether, and pos also the force of gravitation is transmitted by a rotatory motion, though, as Laplace points out, the velocity of the gravitation mu t be at least 7,000,000 times that of light

(2) That it is filled with an ether more analogous to ordinary satter, which offers resistance, or with a highly rarefied gaseous

matter, which ouers resistance, or with a nightly matter gaseous medium similar in constitution to our atmosphere.

(3) That it is filled with ether, through which innumerable solid bodies of comparatively small size fly singly or in swarms. When they encounter one another, a gas, or a planet, they become laminous, and present the appearance of fireballs, become laminous, and present the appearance of fireballs, meteorites; shooting airs, neteoricy comets, neterice warms, meteoried dust gives rule to the phenomenon of the aurous boreals. The theory has recently been much extended and boreals, the theory has recently been much extended and the control of th

continue indefinitely

If the second hypothesis be true, the resistance, however slight it may be, will tend to retard the motion of the planets. In the case of the earth the friction between the outer layers of the atmosphere and the medium will retard the rotation of the earth, and increase the length of the day. There will also be a to decrease the velocity, and therefore to lengthen the year; but, on the other hand, if the tangential velocity he decreased while the attraction of the sun remains the same, the earth will fall towards the sun, the mean distance will decrease, and therefore the time of revolution will be shortened

If the third hypothesis be true, the rain of meteorites will have no effect on the rotation of the earth, but will tend to

lessen the orbital velocity

lesses the orbital velocity. Lapinee has disquised some consequences of the second hypo there in "Mécanique Céleste," vii 6, on secular variations in the novement of the moon and cards which might be produced by the resistance of an etheral medium spread round the sun distance from the sun, and that the resistance verse as the square of the velocity. He concludes that the acceleration produced by the resistance of a fluid either on the mean motion of the moon is, up to "the present time," in sersible, and that the acceleration produced by the same either on the motion of the earth would he loss than 1/100 of the earth would he loss than 1/100 of the relative to the control of the relative to t tended to other planets and to comets in x. 7, where it is shown that the distance at penhelion remains unchanged, and the only alteration in the orbit is a decrease in the length of the major

attention in the orbit is a sections: In the control was a sand in the eccentricity.

The question is discussed from a mathematical point of view in several text-books (e.g. Tait and Steels, "Dynamics of a Particle," pp 279, 379), but in all cases the mathematics are somewhat difficult, and various assumptions have to be made to render the solution possible

In the case of the earth, if the resistance of the medium be small, the orbit may be considered to be circular, more espe-cially as it follows from Laplace's results that the error introduced decreases with the time, since the orbit becomes more nearly circular. The following brief abstract of the popular treatment suggested by G A Hirrs in his "Constitution of Pisapec Celeste," pp 104-108, with the substitution of English values, and the extension of the results to the meteoric hypo-

thesis, may be not without interest at the present time.

Many of the data are so uncertain, that the rough approximations by which mathematical difficulties are avoided probably produce no great loss of anthmetical accuracy in the results

produce no great loss of arithmetical accuracy in the results. The ver wrave of the earth at the end of any period is equal to the ver wave at the commencement of the period, less the ver wave lost owing to the revistance of the medium, and increased by the ver viva due to the fall towards the sun Transposing. and dividing by M/2-

$$v_r^2 = v_t^2 + v_t^2 - v_t^2$$
.

Writing S for the attraction of the sun, and resolving along the radius vector A-

$$v_o^2/\Lambda_o = S$$
, $v_o^2 = S\Lambda_o$
After a time t .

$$v_t^3/A = S \frac{A_s^3}{A_s^3}, \quad v_t^3 = SA_s^3/A_t$$

The acceleration towards the sun is expressed by

$$\frac{d^2A}{dt^2} + S \frac{A_c^2}{AC} = 0;$$

and integrating.

$$v_{I}^{1} = 2 \text{SA.} \begin{pmatrix} A_{\sigma} - 1 \\ A_{f} - 1 \end{pmatrix}$$

Substituting and reducing,
 $v_{I}^{2} = v_{\sigma} \begin{pmatrix} A_{\sigma} - 1 \\ A_{f} - 1 \end{pmatrix}$.

Hence the ves viva lost, owing to the resistance of the medium, is one-half of the vis viva gained by falling through (A. - A.) towards the sun, and the presence of a very slightly $(\Lambda_0 - \Lambda_0)$ towards the sun, and the presence of a very signtly resisting medium surraces the velocity of the earth in its orbit. This increase is easily expressed, since, by Kepler's third law, we may replace $(\Lambda_0/\Lambda_0)^3$ by $(T/T_0)^3$, where T_*T_0 are the periodic times at the beginning and end of the period,

$$\therefore \ v_{r}^{2} \approx v_{r}^{2} \left\{ \begin{pmatrix} T_{r} \\ T_{r} \end{pmatrix}^{\frac{1}{4}} - 1 \right\}.$$

But the vis zero lost owing to the resistance is equal to the work done in forcing the sphere against the resistance of the medium through the distance passed over by the earth during the time. We may assume for simplicity that during the last 2000 year the length of the year has shortened by five second; and since the change in the radius vector would be very small, that A = 233000, where a is the radius of the earth, and hence that the distance through which the earth has passed is

2r 233002 2000
M. Hirn, by theory and experiment, shows considerable reason for believing that the formula of Hutton, for the resistance of a medium in terms of the density δ , gives a result not far from the truth. Hence

$$\begin{array}{ll} \text{O.451} & \sim (\pi a^5)^{1.1} \times \delta \times v_{\nu}^{-1} \times 2\pi \, 23\, 30\, oa\, 2000 = \frac{M v_{\nu}^{-1}}{2} \left(\frac{T_{\nu}^{-1}}{T_{\nu}^{-1}} - 1\right), \\ \text{where} & \left(\frac{T_{\nu}}{I_{\ell}}\right)^{\frac{1}{2}} - 1 = \left(1 + \frac{5}{31558150}\right)^{\frac{3}{2}} - 1 = \frac{1}{9467445} \\ & \frac{1}{8} = (\log^{-1}14\, 32\, 278) \times 4\pi^{-\frac{3}{2}}/\Delta, \end{array}$$

where A is the absolute mass of unit volume of the material of the earth

. .
$$\frac{1}{8} = 5.64 \times 10^{14}$$
 cubic feet.

M Hirn further points out that this decrease of five seconds in the length of the year during a period of 2000 years would be accompanied by a change in the longitude of the earth of more than 205", an amount quite inadmissible since the time of Hipparchus, while the above results have shown that, to pro-duce an acceleration so small as this, the medium must have a duce an acceleration so small as this, the medium must have a ranty such that one pound occupies 564 billions of cubic feet And the volume occupied by a pound of the gas very nearly varies inversely as the number of seconds gained in the periodic When we pass on to consider the retardation caused by the

action of meteorites, we lose the guidance of M. Hirn, but are able to refer for data to Prof Lockyer's treatise About 30 miles, or 158,400 feet per second, may be taken as the average velocity of meteorites (p. 68) Suppose the earth at rest, and struck by a meteorite weighing one pound with this velo-

city, the vis viva of the blow would be $\frac{1}{2}$ (158400)2=3.98 × 108

absolute foot-pounds (p. 64).

But the earth is moving in its orbit with a velocity of 18 4 But the earth is moving in its oront with a velocity of 18-d miles, or 97, 30 feet per second, hence, of every three meteor-ities we may presume that two strike the front, and one the back bemisphere. Further, the velocity of the earth is, in the one case, to be added to, and, in the other case, subtracted from, the

Suppose that a meteorite weighing one pound has the specific heat 0.2, which is about double of that of iron, to raise it from - 270° C. to 2000° C., 454 units of heat are required, which are equivalent to about 454 \times 44758 = 2 \times 10² absolute foot pounds of work—a quantity which may be neglected, in comparison with the total vis river of the meteorite.

the total vis viva of the meteorite.

The weight of meteorites var.es from tons to small specimens (p. 19), and hence we must assume an average weight of pounds. According to Newcomb, 20,00,000 meteorites a day enter our atmosphere (p. 69). We may again assume that the action has continued for 2000 years, and caused a shortching in

the periodic time of five seconds

The vis viva of the impacts,

$$\mu < 4.58 \times 10^9 \times \frac{20000000}{3} \times 365 \times 2000$$

must be equal to the rus prous lost by the earth,

$$\frac{1}{3}Mv^2$$
 $\left\{ \begin{pmatrix} I_0 \\ I_1 \end{pmatrix} = 1 \right\}$, which is $\frac{4\pi a^4}{6} < 10.86 < (97130)^2$, $6 > 9467445$

$$\mu = \frac{1.95 \times 10^{11}}{1.115 \times 10^{19} \times 2000 \times 9407445}$$
= 9240 pounds, or over 4 tons

In this case, also, the average mass of the meteorites varies inversely as the shortening of the periodic time. Thus, if the average weight of ineteorites is 9 pounds, the shortening would be only o oo5 second-an amount probably mappreciable SYDNEY IUPION

THE FLOWERS OF THE PYRENELS AND THEIR FERTILIZATION BY INSECTS

THE observations described in this work were made in the Vallee de Luz (Ilautes Pyrénces, France), in August 1889 Vallee de Lus (liautes Pyrenes, France), in August 1899, and June 1890, between 1900 and 2200 metres altitude. The notation of a fathern flowers. In the last of the visits, date and altitude are always noted, and in many cases particulars are given about the special habits of insects in visiting flowers. Many of the mentioned insects were not before seen visiting. flowers

The contrivances by which the flowers are fertilized are de-The contributes by which the howers are tentiled and de-scribed for the following species: Merendela Bulbocadium, Asphadelus albus (lepidopterophilous, proterogynous), Hyacin-thus amethysismus (proterandrous, adapted to long-tongued bees), It prenates, Antireheum tempervirens, Linaria origanistila (adapted to bees, with special entrance for Lepidoptera or joha (dapted to bees, with special cutrance for Lepidoptein or Bombylide). Livaria spranica, furnissis spranica, fusionissis spranica spranica, divinissis spranica spranica with special estimates for Lepidoptein, Taurium Pyrinineam with special estimates for Lepidoptein, Taurium Pyrinineam monipatulanus (lepidopterophilosu), Alines sp. NO. 1131, VOL. 44

The annual report of the Local Lectures Syndicate, published The annual report of the Local Lectures Syndicate, published in the Unsersity Reporter of June 32, records a large amount of useful work in so-called University extension. The number of course given in 189-01 was 153, with an average attendance course given in 189-01 was 153, with an average attendance to the course given in 189-01 was 189-01 with 189-01 was 18

the work of the Syndicate, and it seems not improbable that if a grant of this nature is made permanent a considerable demand will be made upon their staff of lecturers. In Devonshire they have provided at the request of the County Council a Lecturer on Chemistry and a Lecturer on Mechanics, in each case with special reference to applications to agriculture. The lectures in chemistry were given at six centres, those in mechanics at five. The average weekly attendance was—at lectures about 40, at classes about 25, at each centre In all, 64 students presented themselves for examination, of whom 44 passed, 14 obtaining distinction. The audience comprised a number of hoys from elementary and secondary schools, and some working men and farmers and schoolmasters, in addition to the usual mixed audience The lectures were of necessity arranged rather hurriedly, without sufficient time for the local authorities to complete their organization, and they can only be regarded as an experiment. The Syndicate have reason to think that the experiment has been as successful as under the circumstances

could be expected could be expected.
"Having regard to the probability of a considerable demand for lecturers in connection with the County Councils, the Syndicate have added to their list several new lecturers whose attainments mark them out as suitable for this work. And in attaments mark them out as suitable for this work. And in order that the lecturers may have practical acquainance with the applications of their science to the uses of agriculture, the Syndicate have arranged that they should pay vaits to farms of various characters and to the experimental farm at Woburn Mr. H. Robinson, of Downing College, the assistant to the Professor of Chemistry. Mr. Robinson conducts also a course of laboratory work with the lecturers, with special reference to agricultural investigations. The Syndicate desire to express their grateful sense of the help which Prof. Liveng and Mr. Robinson have so liberally given The provision of teaching Robinson have so liberally given The provision of teaching connected with agriculture appears to the Syndicate to be so important for the training of students who may become lecturers on their staff, that they will endeavour to secure a continuance of this assistance, and are prepared to devote a portion of their

of this abstance, and are prepared to devote a portion of midds to the purpose.

The Ords Sensoridate for the year shows that 6 D Sc degrees have been conferred, 19 M D degrees, 72 M B, and 70 B C.
These figures bespeak the steady growth of the faculties of science and medicine, the numbers in medicine herg larger than in any previous year.

SOCIETIES AND ACADEMIES. LONDON.

Royal Society, June 11 - "On Electrical Evaporation" By William Crookes, F.R S

It is well known that when a vacuum tube is furnished with If its Well known untar when a vacuum tour it accumum to minemal plainum electrodes, the adjacent glass, especially near the negative pole, specify becomes blackened, owing to the deposition of metallic plainum. The passage of the induction current greatly stimulates the motion of the residual gaseous molecules; those condensed upon and in the immediate neighborhood of the condensed upon and in the immediate neighborhood or the condensed upon and in the immediate neighborhood or the condensed upon and in the immediate neighborhood or the condensed upon and in the immediate neighborhood or the condense of the conden bourhood of the negative pole are shot away at an imm speed in almost straight lines, the speed varying with the degree of exhaustion and with the intensity of the induced current. of exhaustion and with the intensity of the induced current. Platinum being used for the negative pole, not only are the gaseous molecules that away from the electrode, but the passage of the current so affects the normal molecular motions of the metal as to remove some of the molecules from the sphere of metal as to remove some of the molecules from the spiner of attraction of the mass, cassing them to fly off with the stream of gaseous molecules proceeding from the negative pole, and to adhere to any object near it. This property was, I believe, first pointed out by Dr. Wright, of Yale College, and some interesting experiments are described by him in the American Journal

ing experiments are described by him in the American Yourney of Science and Arts. The process has been much used for the production of small mirrors for physical apparatus

This electrical volatilization or evaporation is very similar to ordinary evaporation by the agency of heat Cohesson in solids varies according to physical and chemical constitution, thus every kind of solid matter requires to be raised to a certain temperature before the molecules lose their fixity of position and are rendered liquid, a result which is reached at widely different temperatures. If we consider a liquid at atmospheric pressure—say, for instance, a basin of water in an open room—at molecular distances the boundary surface between the liquid and the super-incumbent gas will not be a plane, but turbulent like a a stormy ocean. The molecules at the surface of the liquid dart to and ocean. The molecules at the surface of the liquid dart to and fro, rebound from their neighbours, and fly off in every direction. Their initial velocity may be either accelerated or retarded, according to the direction of impact. The result of a collision may drive a molecule in such a direction that it remains part and may drive a molecule in such a direction that it remains part and parcel of the liquid, on the other hand, it may be sent upwards without any diministion of speed, and it will then be carried beyond the range of attraction of neighbouring molecules and By off into and mingle with the superincumbent gas. If a molecule of the liquid has been driven at an angle with a velocity not sufficient to carry it beyond the range of molecular attraction of

sufficient to carry it beyond the range of molecular attraction of the lequel, it amy still escape, since, in its occasion upwards, a fee lequel is any still escape, since, in its occasion upwards, a temporary wait may be converted into permanent residence. The intrinsact velocity of the molecules is internified by heat and diminished by cold. If, therefore, we make the temporature and the still escape the control of the such case of the lequel are rendered longer and the force of impact greater, and thus the escape of nolecular into the upper region of gas su increased, and we say

that evaporation is augmented.

If the initial velocities of the liquid molecules can be noreased by any other means than by raising the temperature, so that their escape into the gas is rendered more rapid, the result may be called "evaporation" just as well as if heat had

result may be called "evaporation" just as well as it heat has been applied.

been applied.

been applied to the property of t

If a gaseous medium exists above the liquid or solid, it prevents to some degree the molecules from flying off. Thus both ordinary and electrical evaporation are more rapid in a vacuum than at the ordinary atmospheric pressure.

I have recently made some experiments upon the evaporation of different substances under the electric stress,

of different substances under the electric stress. Evolporation of Cadminum—A. U shaped tube was made, Evolporation of Cadminum—A. U shaped tube were at the extremittee of each limb, and in each bulb was asspended from a small platinum hook a small lump of cadminum, the mat-la having been cast on to the wire. The whree were each weighted with and without the cadminum. The tube was exhausted, and with and without the cadmium. The tube was exhausted, and the lower half of the tube was inclosed in a metal pot containing parafilm wax, the temperature being kept at 230° C during the continuance of the experiment. A deposit around the negative pole took place almost immediately, and in five minutes the build surrounding it was opaque with deposited metal. The positive pole with its surrounding fluminosity could be easily seen the whole time. In thirty minutes the experiment was stopped, and after all was cold the tube was opened and the wires weighed The results were as follows .-

Cadmium volatilized in 30 mins. . 7 52 .. Finding that cadmium volatilized so readily under the action of the induction current, a large quantity, about 350 gra., of the pure metal was scaled up in a tube, and the end of the tube containing the metal was heated to a little above the meltung-

Third Senes, vol xii. p 49, January 1877, and vol. xiv p 169, September 1877

point; the molten metal being made the negative pole, in a few hours the whole quantity had volatilized and condensed in a thick layer on the far end of the tube, near, but not touching,

thek layer on the far end of the tube, near, but not touching, the positive pole. Polastikuston of Solver.—Silver was the next metal experimented upon. The apparatus was similar to that used for the calmium experiments. So the solution of the calmium experiments are solution of the sol ment, were as follows --

Original weight of silver	18 14 grs.	24 63 grs
Weight after the experiment	18 13 ,,	24 44 1,
Silver volatilized in 14 hours	. 001	0 19

In this tube it was not easy to observe the spectrum of the negative pole, owing to the rapid manner in which the deposit obscured the glass. A special tube was therefore devised, of the following character—A silver rod was attached to the platinum following character —A silver rod was attached to the platinum pole at one end of the tube, and the administing power has the and the side. The end of the tube opposite the silver pole was at the side. The end of the tube opposite the silver pole was rounded, and the spectroscope was arranged to observe the light, as the silver pole was a silver pole was a silver pole was already to the silver pole to the silver pole was a view of fixed in obstruction to the light, as none was deposited except on the side of the tube surrounding the silver, at a vacuum gwing a dark space of about 3 mm from the silver, a gave a very brilliant spectrum. The spack from silver poles in an was brought into the same, field of view as the vacuum glow, by means of a right angled prism attached to the spectroscope, and the two spectra were compared. The two strong green lines of silver were visible in each spectrum, the measurements taken of their wave-lengths were 3344 and 3675, numbers which are so close to Thakn's numbers as to leave no doubt that they are no close to lankin numers are so leave no cloud that they are the silver lines. At a pressure giving a dark space of 2 mm the spectrum was very bright, and consisted chiefly of the two green lines and the red and the red and cere hydrogen lines. The inter-calation of a Leyden jar into the circuit does not materially increase the brilliancy of the lines, but it brings out the wellincrease the oritinacy of the lines, but it brings out the well-known are lines. At this pressure not much allow fits off from the pole. At a higher vacuum the luminosity round the silver pole gets less and the green lines vanish. At an exhaustion of about one-millionth of an atmosphere the luminosity is feeble, the ailver pole has eracily the appearance in boung red-hot, and the volatilization of the metal proceeds rapidly!

the vointilization of the metal procests rapidly.

If, for the negative electrode, instead of a pure metal such as cadmium or silver, an alloy was used, the different components might be shot off to different distances, and in this way make an electrical separation—a sort of fractional distillation. A negative ciectrical separation—a sort of fractional distillation. A negative terminal was formed of clean brass, and submitted to the electrical discharge in man o, the deposit obtained was of the colour of brass throughout, and on treating the deposit chemically Loyald discrete and control of the c I could detect no separation of its component metals, copper and

A remarkable alloy of gold and aluminium, of a rich purple A remarkable alloy of gold and aluminum, of a rich purple colour, has been kndly sent me by Prof Robert-Auster Gold being very volatile in the vacuum tube, and aluminium almost fixed, this alloy was hiely to give different results from those yielded by brass, where both constituents fly off with almost equal reachness. The Au-Al alloy had been east in a clay tube, in the form of a rod 2 cm. long and about 2 mm in dismeter

in the form of a rod a cin. long and about x mm in diameter.

I have he action producing violations, the "right last" is confined to the superficial layers of molecules only. The most indicately assesses, or confidence of the co

It was scaled in a vacuum tube as the negative pole, an alumnium pole being at the other side Part of the alloy, where it poined the platinum wire passing through the glass, was closely surrounded with a narrow glass tube A clean glass plate was surponded with a narrow glass tube. A clean glass plate was supported about 3 mm from the rod of alloy. After good exhaustion the induction current was passed, the alloy being kept negative. Volatilization was very slight, but at the end of half an hour a faint purple deposit was seen both on the glass plate and on the walls of the tube. On removing the rod from the apparatus it was seen that the portion which had been covered by the small glass tube retained its original purple covered by the small glass tube retained its original purple appearance, while the part that had been exposed to electrical action had changed to the dull white colour of aluminium, Examined under the microscope, the whitened surface of the Austen alloy was seen to be pitted irregularly, with no trace of

crystalline appearance. This experiment shows that, from an alloy of gold and aluminium, the gold is the first to volatilize under electrical influence, the aluminium being left hehind. The purple colour of the deposit on glass is probably due to finely-divided metallic gold The first deposit from a negative pole of pure gold is nurnle then turns to green, which gets darker and darker until metallic lustre of polished gold appears

If we take several liquids of different boiling points, put them under the same presure, and apply the same amount of heat to each, the quantity passing from the liquid to the gaseous state will differ widely in each case

214

It was interesting to try a parallel experiment with metals, to find their comparative volatility under the same conditions of temperature, pressure, and electrical influence. It was necessary to fix upon one metal as a standard of companson, and for this purpose I selected gold, its electrical volatility heing great, and it being easy to prepare in a pure state

An apparatus was made that was practically a vacuum tube with four negative poles at one end and one positive pole at the with four negative poies at one cut and one positive poie at the other. By a revolving commutator I was able to make electrical connection with each of the four negative poles in succession for exactly the same length of time (about six seconds), by this means the variations in the strength of the current, the experiment lasting syme hours, affected each metal alking.

he exposed surface of the various metals used as negative poles was kept uniform by taking them in the form of wires that had all been drawn through the same standard hole in the drawplate, and cutting them by gauge to a uniform length; the actual size used was 0.8 mm in diameter and 20 mm

long.

The comparison metal, gold, had to be used in each experiment; the apparatus thus enabled me to compare three different metals.

The same of time that the current was kept on the revolving commutator in each experiment was eight hours, making two hours of electrification for each of the four negative electrodes; the pressure was such as to give a dark space of 6 mm

The fusible metals, tin, cadmium, and lead, when put into the apparatus in the form of wires, very quickly melted To avoid this difficulty a special form of pole was devised Some small this difficulty a special form of pole was devised. Some small curcular porcelain basins were made, 9 mm diameter, through a small hole in the bottom a short length of iron wire, 0 8 mm. in diameter, was passed, projecting downwards about 5 mm.; the basin was then filled to the brim with the metal to be tested, and was fitted into the apparatus exactly in the same way as the wires : the internal diameter of the basins at the hrim was 7 mm., and the negative metal filed flat was thus formed of a circular disk 7 mm diameter. The standard gold pole being treated in the same way, the numbers obtained for the fusible metals can be compared with gold, and take their place in the

The following table of the comparative volatilities was in this way obtained, taking gold as = 100 ---

	Ť				
Palladium		109.00	Platinum		44'00
Gold		100 00	Copper		40 24
Silver		82.68	Cadmium		31.00
Lead		75 04	Nickel		10 00
Tin		56*96			10.40
Brass		51 58	Iron		5.20

In this experiment equal surfaces of each metal were exposed

to the current. By dividing the numbers so obtained by the specific gravity of the metal, the following order is found :--

Palladium	9 00 Copper	 2.23
Silver Tin	7 88 Platinur 7 76 Nickel	2.02 1.29
Lead	6 6t Iron	 0 71
Gold Cadmium	5 18 Iridium	0 47

Aluminium and magnesiam appear to be practically non-

Volatile under these circumstances.

The order of metals in the table shows at once that the The order of metals in the table shows at once that the electrical volatility in the solid state does not correspond with the order of melting-points, of atomic weights, or of any other well-known constant. The experiment with some of the typical metals was repeated, and the numbers obtained did not vary materially from those given above, showing that the order is

not likely to be far wrong.

It is seen in the above table that the electrical volatility of silver is high, while that of cudmium is low. In the two earlier experiments, where cadmium and silver were taken, the cadmium negative electrode in 30 minutes lost 7 52 grs , whilst the silver negative electrode in 30 minute lost 7 53 grs, whilst the silver negative electrode in 13 hours only lost of 19 gr. This apparent diverginancy is easily explained by the fact (already noted in the electrical disturbance, takes place when the metal 1 v. is or near the point of lispefaction. If it were possible to form a negative pole 100 central disturbance of moltes silver, then the quantity volatilized in a given time would be probably more than that of cadmium Gold having proved to be readily volatile under the electric

current, an experiment was tried with a view to producing a larger quantity of the volatilized metal. A tube was made having at one end a negative pole composed of a weighed brush of fine wires of pure gold, and an aluminium pole at the other

The tube was exhausted and the current from the induction coil put on, making the gold brush negative, the resistance of the tube was found to increase considerably as the walls became coated with metal, so much so that, to enable the current to mass through, air had to be let in after a while, depressing the gauge

9 mm weight of the brash before experiment was 3,5,456 pr. The distone current was kept on the timb for 143 hours at the end of this time the tube was opened and the brash moved. It now weighed 32,5613, showing a loss of 2,932 grs when heated below redness the deposited film of gold was easily removed from the walls of the tube in the form of very brilliant.

After having been subjected to electrical volatilization, the After having been subjected to electrical volatilization, ine appearance of the residual piece of gold under the uncroscope, using a ½-inch object-glass, was very like that of electrolytically deposited metal, pitted all over with minute hollows.

This experiment on the volatilization of gold having produced the control of the control

This experiment on the volatilation of glot naving produced good coherent films of that metal, a similar experiment was good coherent films of that metal, a similar experiment was referring to the table it will be seen that the electrical volatility of platians in such lower than that of gold, but it was thought that by taking longer time a sufficient quantity might be volatilized to enable it to be removed from the tube.

volatilized to chance it to be removed from the three.

The vacuum tube was exhausted to such a point as to give a
dark space of 6 mm, and it was found, as in the case of gold,
that as a coating of metal was deposited upon the glass the
resustance rapidly increased, but in a much more marked degree, resistance rapidly increased, but in a much more marked degree, the residual gas in the tube apparently becoming absorbed as the deposition proceeded. It was necessary to let a little air into the tube about every 30 minutes, to reduce the vacuum. This appears to show that the platinum was being deposited in a porous spongy form, with great power of coduling the residual porous spongy form, with great power of coduling the residual

Heating the tube when it had become this way non-conducting liberated sufficient gas to depress the gauge of the pump 1 mm., metrace sumeters gas to depress the gauge of the pump I mm, and to reduce the vacuum so as to give a doft, space of about the current for ten minutes the tube again refused to conduct, owing to aboroption. The table was again heated, with another liberation of gas, but much less than before, and this time the whole was re-absorbed on cooling. The current was kept on this tube for 25 hours; it was then

opened, but I could not remove the deposited metal except in

small pieces, as it was brittle and porous. Weighing the brash that had formed, the negative pole gave the following results:-

Another experiment was made similar to that with gold and pintanum, but sing silver as in negative pole, the pure metal being formed into a brush of fine wires. Less gas was acceluded during the progress of this experiment than in the case of deposited freely, and the vacuum was easily kept at a dark space of 6 mm. by the very occasional admission of a trace of sir In 20 hours nearby 3 gm of silver were volatilized. The deposited of airser whether the work of the contraction of the c

Chemical Society, June 4 — Mr W Crookes, F R S, VicePresident, in the chair — The following papers were read — The
unlocaliar refaction and dispersion of warious substances in soil
tion, by Dr J H Gladstone, F R S. The paper is a continuation
of that laid before the Society in March Ists, and deals with solid
and gaincian substances that have been dissolved in water and other liquids for examination. The results are given in several tables. In the case of organic compounds, the theoretical and tables In the case or organic compounds, the theoretical and experimental numbers are frequently in close agreement Hydrogen chloride, bromide, and nodide give figures for the molecular refraction and dispersion much higher than the sum of the hydrogen and halogen as determined from the paraffin of the hydrogen and naiogen as determined from the paramic compounds, and the values rise as the dilution becomes greater Selenious and selenic acids afford optical values much less than what would be expected from the known values of their con-situents. Metaphosphoric acid does the same The data relating to solutions of salts and alkalies will afford material for a revision of the refraction equivalents of the different metals, and of the electro negative elements with which they are combined.

Ammonia, in contrast with the hydrides of chlorine, bromine, and todine, appears to be uniform in its optical properties, whatever the strength of the solution. The refraction equivalents of cerum, didymum, and lanthanum were found about 12'4. 16 4. and 15 5 respectively The molecular refraction for 124, 16 4, and 15 5 respectively. The molecular retraction for CIO₃ in its sails dissolved in water come-out at about 18 3, that for BrO₃ at 24,9, and for IO₃ at 3,8 —The nature of solutions as elucidated by a study of the densities, heat of dissolution, and freezing-points of solutions of calcium chloride, by S Urckering. The curves representing these properties were examined in the same way as those for sulphuric acid, and similar conclusions are drawn—namely, that changes of curvature, which occur at certain points which are the same whatever property is examined represent the existence of hydrates in solution. The simplest hydrates indicated consist of CaCl, with 6, 7, and 8H₂O. more complex hydrates also exist, as in the case of sulphuric acid—Note on a recent criticism by Mr ydney Lupton of the conclusions drawn from a study of various Sydney Lupton of the concusions drawn from a sawy or various properties of sulphuric acid solutions, by S. U. Pickering. Mr. Lupton (Phil Mag, xxxii 418) applies a single parabolic equation to a portion of one of the author's sulphuric acid density curves, where a change of curvature was supposed to exist, and shows that it represents the results accurately if the experimental error is of a certain magnitude. This magnitude is between error is of a certain magnitude. This magnitude is between 1000 and 10,000 per cent greater than the ascertaned magnitude, and the equation represents all errors of like signs as grouped together. Such a representation cannot disprove the existence of the particular change of curvature, under examinaexistence of the particular change of curvature under examina-tion, still less that of the 101 others examined by the author. The hydrate on which Mr Lupton considers that his investiga-tion throws "very grave suspicion" happens to be the one which the author has isolated in the crystalline condition. In the dis-cussion which followed, Prof. Raminay doubted the validity of Mr cussion which followed; Prof. Raminay doubted the validity of Mr Pickering's methods of differentiating his curves His own experience was that it was impossible to obtain results near than 20 r 3 per cent. to the truth. Dr. Armstrong said that he was prepared to believe in the existence of hydrates in solution, but could not imagine that the 102 breaks in the sulphurio acid curves, for mple, could be interpreted as evidence of as many distinct He was inclined to think that the breaks might be due to change both in the complex water molecules and the sulphuric acid. He was inclined to believe that the hydrate, to which Mr. Lupton's conclusions related, did not begin to form

its point of fusion. Dr. Morley said that a break in the curve should indicate that some new hydrate had just begun to form, should indicate that some new hydrate had just begun to form, but need not show what that hydrate was. Thus, a liquid of but need not show what that hydrate had the head of t curves, which themselves represented the results of other experidrawn, and the scale of the co-ordinates carefully chosen, if the results were to be satisfactory, and probably the conclusions arrived at depended in a large measure on the details of this preliminary adjustment. In the case of the more striking clianges in direction and curvature which were clearly visible in the original curve, the various differential curves did not add much to the information it supplied. He thought that the evidence alforded by these secondary curves of changes of curvature, not otherwise detected, was of the most untrustworthy character Mr Pickering said that Mr Lupton's equation represented the rate of change of the densities as a straight line, while the figure which the actually observed rate of change formed was as different from a straight line as possible. The figures here referred to were the first differential figures (rate of change) deduced directly from the determinations themselves, the question of ducetly from the determnations themselves, the question of the accuracy attentible in differentiating graphs, hasted by Prof Ramasy, did not apply He thought that Frof Armaly hasted by the professional professiona high temperatures The multiplicity and complexity of the hybrates indicated must enhanger the acceptance of his conclusions amongst chemists, and he was perfectly ready to accept any other explanation of the changes with weaks oblitions—

P-thylic au-dimethyl ac diacctylpinnelate and its decomposition-products, by Dr. F. S. Kipping, and J. F. Mackeniae. THE UNITED STATES ENTOMOLOGICAL COMMISSION.

Fifth Report of the United States Entomological Commission on Insects Injurious to Forest and Shade Trees By Alpheus S. Packard, M.D., Ph.D

TERY valuable Reports have been presented by the United States Entomological Commission from time to time. Among these may be mentioned that upon "The Rocky Mountain Locust," prepared by Prof. Riley in 1878, which is a most exhaustive record of the habits of this terrible pest, and of methods of prevention and remedies against its attacks Later on, an equally valuable and instructive Report was submitted with regard to the cotton worm (Aletta argillacea), very destructive to the cotton plant, whose crop it has reduced in some seasons from 30 to 75 per cent in the principal cotton-producing States. Both these elaborate works, as might be expected from their authors, Prof Riley and Dr. Packard, who practically constituted this Entomological Commission, are full of interesting experiments, ingenious contrivances, and subile devices, to circumvent the insect hordes advancing with the insistance of invading aimies.

This Report upon "Insects Injurnous to Forest and Shade Trees" is perhaps not so exciting or painfully interesting, as the harm caused to trees is not so directly felt as that occasioned to various food crops and other crops of the field by locusts and caterpillars innumerable, and the name of the insects described therein is legion, and their individual mixcheft is comparatively small

As Dr Packard says, "a volume could be written on the insects invigo on any single kind of tree, and hereafter it may be expected that the insect population of the olds, elim, popular, pine, and other trees will be treated of monographically." Kaltenbach, in "Die Pflannenfemde, and ser Klasse der Insekten," gives accounts of 537 European species of insects injurious to the oak, 107 to the elim, and 396 to the willow. Perris, a French observer, has recorded no less than 100 species of insects found upon the maritime pine.

The attacks of insects upon forest trees and upon shade trees, or trees planted for shade and ormanentation in parks, streets, and other public places, are becoming far more numerous and serious, just as in the case of all cultivated crops under the sun. In the United States these attacks are creating intense interess, as the forests are of the highest commercial importance, and have been extensively decreased by clearing, by wanton and accidental fires, and other causes. This Report, then, is opportune, and must be of great service, as it demonstrates the sources of the influres, and suggests means of preventing them or of dimunishing them.

The French, German, Austrian, and Italian Departments of Agroculture are giving much attention to this subject, for it is found that the forest trees of these countries are becoming more liable to harm from insects. In Great Britain some kinds of trees, notably of the pine tribe, have suffered much damage from insect intherto unknown, or, at least, not reckoned as injurious.

There are, without doubt, many others unsuspected in British woods and forests, slowly but surely working great mischief.

Dr. Packard shows that trees are attacked in every part and in every conceivable manner by insects. Their roots, leaves, bark, fruit, and twigs are all more or less subject to their visitations The most curious of those which affect the roots is the "seventeen year" Cicada, whose larvæ remain for over sixteen years attached to the rootlets of the oak, other forest trees, and fruit trees, as the pear and apple According to Prof Riley, these larvæ are found at a great depth, sometimes as much as to feet below the surface The female, resembling a locust, deposits long slender eggs in an unbroken line upon the terminal twigs of oak and other trees in May and June Sometimes the twigs are so "badly stung by this ovinosition that the trees are seriously injured. The length of wood perforated on each branch sometimes varies from one to two and a half feet, averaging probably eighteen inches, and appearing to be the work of one female. From the eggs the larve hatch out in six weeks and drop to the ground, in which they live, sucking the roots of the trees for nearly seventeen years, the pupa state lasting but a few days

A formidable enemy of the "live-oak" (Quercus virens) is an enormous beetle, Mallodon melanopus, Linn , whose larva, three inches long and an inch in thickness, bores into the roots upon which it lives. As a result of the work of this insect in South Georgia and Florida, " vast tracts, which might otherwise have become forests, enriching the ground with annual deposits of leaves, are reduced to comparatively barren scrub, in which the scattered oak-bushes barely suffice to cover the surface of the sand" The eggs are laid by the beetle in the foot, or collar, of the tree, just below the surface of the ground. It is not known how long the larvæ live, but their life must extend over several years, "since the roots occupied by them grow to a large size, while they show an abnormal development, and become a tangle of vegetable knots In fact, the entire root in its growth accommodates itself to the requirements of the borer within" The effect on the tree is to kill the original stem, which becomes replaced by a cluster of insignificant and straggling suckers, forming, perhaps, a clump of brushwood.

Among the tree-borers, other than beetles, the oak "carpenter worm," the caterpillar of Prionoxystus sobima, Peck, is the largest and most destructive. It is larger and far more abundant than the European caterpillar of Cossus ligniperda, or goat-moth, belonging to the same family of Cossidæ, but it sinks its tunnels deep in towards the heart of the tree, not confining its mischief to the limbs and large branches like the goat-moth caterpillar. Fitch says of this .- " Of all the wood-boring insects in our land, this is by far the most pernicious, wounding the trees most cruelly. The stateliest oaks in our forests are ruined, probably in every instance where one of these borers obtains a lodgment in their trunks." Another species of Cossus, known as Cossus centerensis, bores into poplars. Its appearance and habits also resemble those of the goat-moth, well known in this country

There are numbers of boring beetles, of the families Buprestide, Cerambycide, and Scolytide, whose larvæ

make burrows, passages, and galleries in trees, mainly just under the bark. Of these, the elm-tree borer, Saberda tridentata, is prominent, often killing elm-trees by wholesale, both in forests and in public parks. The larvæ bore in the inner bark, making irregular furrows and tunnels upon the surface of the wood, which "is, as it were, tattooed with sinuous grooves, and the tree completely girdled by them in some places." In the State of Illinois attention was attracted to the gradual decay and death of white elms (Ulmus americanus) in rows in some towns The leaves fell off in the summer, and some of the branches died. Finally, the tree perished altogether. On peeling off the bark, half-grown larvæ of Saberda tridentata appeared in considerable numbers. and the manner in which the bark had been mined by the Saperdas gave sufficient evidence of the cause of the death of the tree. Prof Forbes, State Entomologist of Illinois, says: "From the present appearance of the elms throughout the towns of Central Illinois, it seems extremely likely that this pest will totally exterminate this tree, unless it be promptly arrested by general action." It is recommended that all affected trees should be removed and destroyed in autumn and winter. before the beetles have a chance to emerge from the trunks. This beetle is not quite an inch long, its larva is rather more than an inch in length, having a large flat head.

Fir trees, especially the white pine (Psnus strobus), the yellow pine (Pinus mutis), and Pinus rigida. are much injured by the pine borer or "sawyer," Monohammus confusor. "I have seen," writes Dr. Packard, "hundreds, perhaps nearly a thousand, dead firs, whose trunks were riddled with the holes of these borers." Dr. Packard cites a correspondent of the North-Western Lumberman who reported that "extensive and valuable forests of vellow pine in the Southern States are destroyed by a worm commonly called here a 'sawyer,' or flat head" White pine trees are also much heset by the "wood engraver" bark beetle (Xyleborus xylographus, Fitch), so called because it makes beautifully regular and artistic furrows on the surface of the wood under the bark It is the most common, and probably the most pernicious. of all the insects that infest the forests of white pine in New York State, and of yellow pine in the States south of New York.

A weval, the white pine weval (Pixvodes stroot), frequently spoils the finest white pines in parts of America by placing numerous eggs in the bark of the topmost aboots off fit retes; the larve from these make mines in the wood and pith, causing the shoots to wither and die, thereby occasioning a fork, or crook, at this point. This is a very small insect, not three-quarters of an inch long, and the larve are no thalf as inch in length.

There is a mighty almy of caterpillars of various moths described in this Report, which devoor the foliage of trees of all kinds-in American forests and gardens Several species of Clinocampa and Gasterogacha, of the Bomby-cida, assail oak, willows, ash, chestnut, apple, and pear trees. These are termed "tent" caterpillars, as they live in webs of a tent-like form, as the Clisocampa Neustria, or lackey moth, in Europe. But the most voracous of categoliars are the "fall web worms" of the moth hypatartria curve, Drury. For instance, in 1886, the

city of Washington, as well as its vicinity, was entirely overrun by them. All vegetation, except that not agree-able to their tasses, suffered greatly. Fine rows of shade trees, which grace the streets and avenues, were leafless in midsummer, and covered with hairy worms. The payements were strewn with modellings of the caterpillars and their webs, which were blown about unpleasantly by the wind.

Because they are hairy they have comparatively fee enemies, among birds at all events. The "English sparrow." Fast becoming as great a nusance in the United States as the rabbit in Australasia, will not look at them, and has driven away by its pugnacity many burds that would eat them Fortunately there are insect enemies which prey upon them, as the Mantis carolina, or "rear horse," an extraordinary insect of the same family as the "praying" mants, and the "wheel bug" (Prioundus cristatus). Several parasitic insects also greatly check the spread of this moth. One by, Telenams bightus, Riley, lays its egg within the tiny egg of the moth, in which all the transformations of the fly take place, and its food and lodging are found. In due time, having cleared out the ear, the five merges.

Mr. Bates, in his graphic account of tropical insects, has pictured many that are made to closely resemble their surroundings, for their preservation and other purposes. In his well-known paper on minurcy, he alludes to the insects known as Phasimidae, or "spective" macets, as especially typical of this adaptation to circumstances, preserved and augmented, as Darwin says, "through ordinary selection for the sake of protection." Mr Wallace brings forward the Phasimidae as striking instances of minurcy, remarking that "it is often the females alone that so strikingly resemble leaves, while the males show only a rude approximation."

Species of this family of Phasmidæ are mischievous to trees in America, principally the oak and the hickory. The chief of these is the Diapheromera femorata, Say popularly called "walking-stick," "walking-leaves," "stick-bug," " spectre," " prayrie alligator," " devil's horse," This insect, especially the female, is so like the twigs of trees in colour and appearance, that it is difficult to discover it. It has a habit, too, of stretching out the front legs and feelers. greatly enhancing this re semblance. While the vegetation is green the " walking-sticks " are green; when the foliage changes in the autumn they also change colour; and when the trees are bare of leaves they closely resemble the twigs on which they rest. The eggs are dropped upon the ground from whatever height the females may be, "and, during the latter part of autumn, where the insects are common, one hears a constant pattering, not unlike drops of rain, that results from the abundant dropping of these eggs, which in places lie so thick among and under the dead leaves that they may be scraped up in great quantities." Prof. Riley adds, with regard to these singular creatures and their wonderful resemblance to the oak vegetation upon which they occur, "one cannot help noticing still further resemblances. They are born with the bursting of the buds in the spring; they drop their eggs as the trees drop their seeds, and they commence to fall and perish with the leaves, the later ones persisting, like the last leaves, till the frost cuts them off."

There is not space enough to do more than allude to the sawfiles, another class of insects fearfully injurious to trees of divers kinds Many of these Hymenoptera, as in Great Britain and other European countries. mainly of the genus Nematus, clear off the leaves of forest and fruit trees. Others attack firs, notably some species of Lophyrus and Lyda, as the Lophyrus abietis, Lophyrus pinetum, and Lophyrus pini-rigida, and some of the Lyda. Cameron, in his monograph of the British phytophagous Hymenoptera, states that there are fifteen species of Lophyrus in North America, and that the species of Lyda are common there

Lophyrus abietis and Lophyrus abbotu appear to do the same harm in America to firs as the I ophyrus pini in Scottish fir plantations, whose larvæ not only eat the leaves but the bark of the young shoots, frequently occasioning great losses

An instructive account is given in this work of the effect of temperature upon insects. It is the fashion in Great Britain to say that insects are killed by hard frosts But they are not killed in countries-as America, for examplewhose winters are far more severe Dr Packard, quoting Judeich and Naitsche's "Lehrbuch der Mittel-Europaischen Forstinsektenkunde," observes that " the influence of even very great cold on the normal hybernating stages of our insects is not very great. In the summer of 1854 the 'nun' moth had very generally laid its eggs in Eastern Prussia uncovered on the bark, and these did not freeze in the hard winter of 1854-55 According to the observations of Regener, openly exposed caterpillars of the pine silk-worm endured 10° F The pupa froze at 21' F. the moth at 10 F. According to Duclaux, the eggs of the silk-worm endure well, remaining two months in a temperature of 17° F Great fluctuations of temperature during the winter produce an abnormal interruption of the winter's rest or hibernation, and thus cause the death of many insects" It will be noticed that in all these cases the insects were unprotected, whereas there is generally some kind of protection during the winter for insects in all stages, provided by their instinct.

Not the least useful part of the Report is that treating of remedies for insect attacks, and machines and envines for applying them Arsenical poisons, known as Paris Green and London Purple, are strongly recommended for spraying or syringing trees infested with the larvæ of beetles and sawflies, or the caterpillars of moths. These have been recently introduced into England, being advocated by the Board of Agriculture, but have not been extensively adopted yet, owing to the natural prejudice against the use of poisons. In America they are employed most extensively and with the greatest benefit By means of these the potato beetle (Doryphora decemlineata) was circumvented, and the cotton and boll worms checked, and the onslaughts of many other insects materrally lessened. For Aphides, Scale insects, and other insects which suck the sap of leaves, "emulsions" or washes of soft soap, or "jelly soaps," made directly from fish oil and concentrated lye, or whale-oil soap, are prescribed Also kerosine, naphtha, and petroleum, applied in a fine spray, or mixed with soap and soap jelly, forming "emulsions." These remedies act by contact, being applied principally to insects which do not eat the leaves as well as by making the surroundings unpleasant and solved; everything else is mere child's play.

unbearable. Powdered substances, as pyrethrum, hellebore, and sulphur, are not much employed for forest work, but cases frequently arise warranting their use in a limited way Hellebore, as gooseberry growers in Kent and Cambridgeshire well know, is of especial value against all sawfly larvæ Sulphur is valuable against the red spider (Tetranychus telarius), and is used alone or in connection with emulsions of kerosene.

Numerous machines are in vogue for putting on washes and powders, from the small "knapsack" machine carried on the back to have tanks on wheels, fitted with powerful hand-pumps and long lengths of hose, through which liquids are forced to great heights, for very high trees, tall ladders are used, which are set near the trees, upon which men mount, and direct the hose into the copmost branches For smaller trees and shrubs, a barrel fixed on wheels, having a good force-pump with hose, is adopted Pumps are also fitted into tanks of all shapes and sizes, and moved from place to place by hand or horse-power. To distribute the liquids there are endless nozzles or jets contrived with much ingenuity to send forth fine mists. or sprays, or continuous volumes It will suffice to say that the best of these is the cyclone, or Riley nozzle, which is just being introduced into Great Britain

Foresters, and all concerned in the management of woods and forests, public parks, and gardens, would do well to consult this work for information as to the various insect enemies of trees, and the best means of dealing with them. It is quite impossible in a review to give anything more than a general idea of its scope and nature

PHYSICAL RELIGION

Physical Religion The Gifford Lectures delivered before the University of Glasgow in 1800 By F Max Muller (London Longmans, 1891)

HE present volume, which embodies the author's second course of Gifford Lectures, with notes and appendices, is devoted to the consideration of "Physical Religion," that is the religion which finds its object the Infinite in or behind the phenomena of Nature The author's previous writings have made it clear that for the simplest and most abundant manifestation of this form of religion we must go to the Veda, so his first task in the lectures before us is to tell once more the familiar story of the discovery, the character, and the age of the Veda To this survey four lectures are devoted, and, in conclusion, the author-not without duly considering all that in recent years has been urged to the contrary-reattirms his conviction that the hymns of the Rig Veda cannot have been collected later than 1000 BC

In the sixth lecture the author deals with the evolution of the idea of God It is often supposed-even by philosophers of repute-to be a sufficient account of the earliest form of religion to say that men worshipped stones and other fetishes as their gods But, as the professor well remarks-

"Does it never strike these theorizers that the whole secret of the origin of religion lies in that predicate, their gods? Where did the human mind find that concept and that name? That is the problem which has to be

And he exhibits the process by which Agnı (the Vedic god of fire), from being originally nothing but "the mover," came to be called deva; and it is this word deva which when examined yields the clue to the development. and teaches us a lesson of the highest importance .-

220

"Guided by language we can see as clearly as possible how, in the case of deva, the idea of God grew out of the idea of light, of active light, of an awakening, shining, illuminating, and warming light. We are apt to despise the decayed seed when the majestic oak stands before our eyes, and it may cause a certain dismay in the hearts of some philosophers that the voice of God should first have spoken to man from out the fire. Still, as there is no break between deva, bright, as applied to Agni, the fire, and many other powers of nature, and the Deus opti-mus maximus of the Romans—nay, as the God whom the Greeks Ignorantly worshipped was the same God whom St. Paul declared unto them-we must learn the lesson, and a most valuable lesson it will turn out to be, that the idea of God is the result of an unbroken historical evolution, call it a development, an unveiling, or a puri-fication, but not of a sudden revelation."

The two following lectures are devoted to the detailed following out of the biography of Agni, who appears in a variety of characters as the sun, the fire on the hearth. lightning, the messenger between gods and men, and priest. Finally, divested of his material character altogether, he is raised to a sublimer level as creator, ruler, and judge. The value of this inquiry, into the details of which we have no space to enter, lies in the fact that it involves the refutation of two objections which are frequently urged-with or without knowledge-against natural religion by the professors of so-called supernatural religion. The first is that natural religion, though it may lead men to a conception of "gods," is powerless to suggest to them the conception of God. This is directly contradicted by the history of Agni, whom we can watch, as it were, passing through many stages of growth until he becomes in the end "a supreme god, the Supreme God, till his very name is thrown away, or is recognized as but one out of many names by which ancient seers in their helpless language called that which is, the One and All" Driven from this position, however, the orthodox objector usually takes up another, and contends that the supreme God of natural religion lacks some if not all of the lofty attributes which he is enabled to know and to predicate of his own God by supernatural revelation But Prof. Max Muller's answer to this objection is equally decided .-

"Trusting to the fragments that have been preserved to us in the Veda, to the remains of the most childish as well as the most exalted thoughts, we may say that natural religion, or the natural faculties of man under the dominion of the natural impressions of the world around us, can lead, nay, has led man step by step to the highest conception of deity, a conception that can hardly be surpassed by any of those well-known definitions of deity which so-called supernatural religions have hitherto claimed as their exclusive property

In the ninth ecture the Professor leaves for a while the field of his special studies to glance at the history of religious ideas among other peoples than the Aryas of the Veda. And it is noteworthy that he fully recognizes the pogsibility that Jehovah himself may originally have been

which he alludes to Abraham, the legendary founder of Hebrew monotheism, as if his historical character had never been questioned. It is, of course, perfectly open to any one to believe that Abraham was a real individual. who received a "revelation," whatever that word may be defined to mean (see p. 221); but at the same time, in a course of lectures addressed to an academic audience, it should surely have been mentioned that this is an hypothesis, which Renan, for instance, among Semitic scholars. does not even take the trouble to discuss

In the lecture on the mythological development of Agni, we would call attention to the importance assigned to riddles as a cause of the growth and preservation of mythology. To take a simple example

" After the Arvas in India had once arrived at the conception that fire was apt to consume the fire-sticks, or that Agni had eaten his father and mother, they seem to have amused themselves by asking such questions as, Who eats his own parents? The answers given would then enter upon many details, more or less far fetched, and the question would continue to be asked between young and old people "

And we think that this is a far more natural explanation of the origin and popularity of such stories than the hypothesis, which has no external evidence to support it, that the Aryas were simply ascribing to Agni the atrocitles which they practised themselves

Finally we come to the question, What can a study of natural religion teach us? "Why," answers Prof. Max Muller, "it teaches us that religion is natural, is real, is inevitable, is universal," and he proceeds to exhibit in detail one or two of the more important implications of this great lesson. With regard to miracles, for instance -

"Is it not clear that in the eyes of those who believe in the omnipresence of the Moral Governor of the world, miracles, in the ordinary sense of the word, have become impossible, and that to them either every event is miraculous or no event can claim that name Before the great miracle of the manifestation of God in nature, all other miracles vanish. There is but one eternal miracle, the revelation of the Infinite in the

The Professor then shows by a series of examples that the tendency to ascribe a miraculous birth to the founders of religions is natural and widespread, and asks by what right people claim a different character for the legends of the birth of lesus than for the similar legends told of Buddha and Mohammed The honesty and candour with which the question is stated are specially welcome at the present time, when it is becoming the fashion with ecclesiastical amateurs in Biblical criticism to blow hot and cold, as it were, with the same infallible mouth-that is, to reject the miracles of the Old Testament, but retain those of the New For instance, in a recent manifesto, highly recommended as providing a temporary shelter for the destitution of the semi-reasonable, there is, on the one hand, some tall talk about the imaginative performances of "a dramatizing Jew" in the Old Testament, while, on the other hand, we are gravely informed that "the Church can insist upon the truth " of all that is recorded in the New Testament That this cheap substitute for criticism will eventually be discredited, even in England, we have no a doubt whatever. Meanwhile we cordially recommend the present volume not only for the interest of its subjectmatter, but as an example of the masterly application of the only method which in these inquiries can lead to sure results.

THE KARWENDEL ALPS

Das Karwendelgebirge Von A Rothpletz Separat-Abdruck aus der Zettschrift des Deutschen und Oesterreichtschen Alpenvereins. With Map. (Munchen, 1888.)

THE Karwendel Alps are a mountain mass lying to the north of the valley of the Inn, between Innsbruck and Jenbach, and bounded on the east by the horbach and benached the last and the south roughly by a line drawn along the Hantanalid (the highest part of the valley of that river) to Schwas, in the Innihal This region has been explored and mapped by Herr Rohlpetz, with the assistance of other workers, and it is described as consisting of three roughly parallel ranges. Though their peaks do not attain to a very great elevation, the higher summits ranging from Soo feet to rather over \$200 etet, their grand cliffs of cream-coloured limestone and their pine-clud slopes afford very beautiful scenery.

In this part of the Alps the mountain masses are wholly composed of sedimentary deposits which range from the Trias to the Neocomian The oldest are the Werfener Schichten, a mass of sandy shales and sandstones, often containing numerous flakes of biotite, indicative, in all probability, of the denudation of the crystalline masses which form the floor of the Mesozoic rocks in the Alpine region. They correspond in age roughly with the upper part of the Bunter in Germany and England Then comes the remainder of the Trias, including the Muschelkalk, followed by the representatives of the Rhatic, the Lias, and other Jurassic deposits, and a part of the Neo comian, a marine series from top to bottom. Neither the last nor the Jurassic system attains to a great thickness, but both the Rhætic and the Trias are represented by great masses of rock In the one, the Haupt-dolomit occasionally attains to a thickness of 500 metres; in the other, one member, the Myophorienschuhten, is said to be equally important Careful descriptions of each subdivision, with lists of the more characteristic fossils, are given in the memoir Neither Cretaceous nor Fertiary strata occur to bridge over the interval between the Neocomian and the superficial Glacial or post-Glacial

The physical history of these ranges is made the subpict of an elaborate discussion. Herr Rothplets is of opinion that, at some epoch after the Neocoman and before the commencement of the folding process by which the existing Alpine ranges were upraised, the region was affected by movements which produced a system of faults. In consequence of these, a zone of upheaval was bordered on either side by one of depression. These caused important modifications in the great east and west folds, to which the Eastern Alps are due; the rocks in the two troughs were crushed together, the upheaved tracts were upthrust. A folding plate represents an ideal section of the region after the "piesents an ideal section of the region after the "pieAlpine" movements, side by side with one which shows its present state

There can be no doubt that, in explaning the physical structure of the Alps, we have to take account of much more than the later Tertuary foldings to which the formation of the mountain-chain is die, such as the odd in the pre-Mesonic land-surface, and any important system of faults could not fail to produce varianted effects. Also, it seems indubtable that there were interruptions to the downward movement in parts of the Alpine area during the later Mesonic and the earlier Tertuary times, which may, very probably, have caused faults such as are described by Herr Rothpletz. These, it may be noticed, appear to run obliquely to the general trend of the main folds

Herr Rothplets, in conclusion, expresses an opinion adverse to those geologists who consider that glacters have played an important part in the crosson of valleys, and calls especial attention to the Soensee, a small lake lying in a fold of the Plattenkalls, which, in his opinion, indicates that "the movement of fleutre acted in this case with greater rapidity than the elosive action of streams or glacter".

The geological map is on a scale of 1, 50,000; the separate memoir, of octavo sive, contains 76 pages, with 9 plates and 29 smaller illustrations. It also includes a full list of works bearing on the district. So far as we can judge, it is an elaborate and valuable contribution to the knowledge of a region but little known to English travellers, who, however, occasionally pass very near to it along the migran of the beautiful Achensee

OUR ROOK SHELF

Graphical Status - Two Freatises on the Graphical Calculus and Reciprocal Figures in Graphical States - By Luigi Cremona - Translated by Thomas Hudson Beare, Professor of Fingmeering and Applied Mechanics, Heriot-Watt College, Edinburgh, (Oxford, Clarendon Press, 1890).

I REALINE on this and allied subjects of the Graphical Calculus are not uncommon in our language, but, although nowadays indispensable for engineering purposes, the subject does not flourish in our theoretical courses of instruction.

The theorems of Graphics once stated—that is, drawn out carefully on the drawing board—are obvious, or at least do not lend themselves to verbal written demonstration, so that for purposes of competitive examination, the controlling influence of modern education, the subject of Graphical Statics and Calculation is useless

Geometrical drawing is not taught in our public schools and Universities, and the student in a technical college only requires the bare minimum of Graphics, sufficient to enable him to pass on to practical development; so that we fear the elegant abstract theorems on the use of significant of the control of equations, centrods, rectification and graphical analysis generally, will receive but sight attention.

There is a note of defance in the Author's Preface to the English edition of "Reciprocal Figures in Graphical Statics" (the second treatise) "At a time when it was been also been also been so engineering could be solved by mathematical analysis only, Culmann's genus suddenly created Graphical Statics, and revealed how many applications graphical methods and the theories of modern (projective) geometry possessed," &c.

The preface to "Geometry of Position," by R. H. Graham, must be consulted for the counterblast in favour of Maxwell's claim to the honour of priority.

The History of Commerce in Europe. By H. de B. Gibbins With Maps. (London: Macmillan and Co. 1801.)

THE chief defect of this little book is that the author does not bring into sufficient prominence the geographical element in commercial history. What are the geo-graphical conditions which have favoured the growth of particular industries in special localities? And in what ways have such conditions affected the interchange of commodities between one part of the world and another? Mr Gibbins has not, of course, neglected these questions, but he scarcely seems to have realized that they are of out its exercity seems to have realized that they are of vital importance for the scientific presentation of his subject. On the other hand, his appreciation of the action of historical causes in the development of commerce is excellent; and for a general view of commercial progress his manual will be of much service to students. After an introductory chapter he considers " ancient commerce." by which he means the commerce of the Phoenicians, the Carthaginians, and the Greek colonies. He then deals with the ancient Greek States and Rome as trading communities. Next comes "mediæval commerce," in connection with which he has much that is interesting to say about the Italian cities, the Hansa towns, medizeval trade routes and fairs, the manufacturing centres of Europe, and other topics Under "modern commerce" he treats of the commercial empires in the East, the commercial empires in the West, English commerce from the sixteenth to the eighteenth century, European commerce in the seventeenth and eighteenth centuries, the industrial revolution in England and the Continental wars (1793), modern English commerce, and the development of commerce in France, Germany, Holland, Russia, and the other European States. The maps are very good, and add considerably to the value of the text We may also note that the volume includes a useful series of questions on the various chapters, and two appendices, in one of which there is a list of British produce and manufactures in 1840 and 1889, while the other consists of a table showing the present colonial empires of European Powers.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Nisther can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communication:

The Albert University

The Albert University of her members of the the first course of the first cour

inversity and King's Colleges So long as the matter was in the hands of the Commission, this charter, put forward by the Councils of the two Colleges, was merely one of many suggestions as to the proper form which a new or reconstituted University of London should take. It was notorious that the Councils' support of Sir George Young's scheme did not represent the attitude either of the Professors of the two Colleges or of those throughout the country who have special knowledge of Universities and of the best methods of academical organization.

inquiry into the draft charter propounded by the Councils of

The Royal Commission of 1888 was appointed to inquire ed for the advancement of higher education in The Commission took a large amount of evidence from interested parties—practically none from persons outside the London institutions concerned—and recommended that the University of London should be invited to meet the needs set forth in such documents as the draft charter of the Albert University, by some modifications of its constitution and procedure. In the event of a failure on the part of the University to do this, the Commissioners recommended that the matter should be

referred back to them My sup ort of the claim of University and King's Colleges to be incorporated as some kind of University has always depended on the assumption that no Commission or other serious authority on the assumption that no Commission or other serious authority could possibly seccede bindily, and without full consultation of the best authorities in the land, to the scheme embodied in the Albert University draft charter. The Commissioners took, it seems to me, the only rational view of that charter—namely, that it might serve as a suggestion to the University in Burlington Gardens for a reform which would meet, at any rate, some of the objections raised to the existing constitution of the latter

body body
Lord Cranbrook, however, seems anxious to burry on the
shelwing if not the solution of the University of London question.
Instead of referring the matter back to the Commissioners, he
takes the matter out of their hands. The Commissioners have
never reported in anxioner to the question at bifore them. No
one knows whether they think any, and, it so, what kind of

new University is required in I ondon.

Having failed to actile the question for the time being by such a reform of the University in Burlington Gardens as Mr. Dyer a retorn to the University in purington carteens as on; Jyer advocates, the Commissioners ought—according to their own recommendation—to have been allowed to proceed further "It is now ascernage," they would have said, "that the existing University of London will not reform uself in the way we have suggested what not of University shall we now recommend, if any?" They might have suggested the coercion of the Convocation of Burlington Gardens by an Act of Parliament; or they cation of burington varieties of an Act of ranament; for unight have—after inquiring from authorities in Oxford, Cambridge, Dublin, Edinburgh, and wherever else some understanding of the nature and objects of Universities happens by chance to dwell—recommended the formation of a professorial University in London similar to those of Scotland and of

Germany.

I confess that it has always been my hope, though not my expectation, that they would take the latter course. I am sure that if they had proceeded to take the evidence of experts in University matters, and had not attached undus importance to

I guite agree with Mr. Dyer that it is little short of monstrous for the Government to set up in London two such organizations as Burlington Gardens and the federal Albert, there is the strongest reason for insisting that there shall be only one of them, whether Convocation like: it or not

Meanwhile, we are no nearer than we were seven years ago to the formation in London of a Senatus Academicus which shall retain in the metropolis—in contact with its statesmen, lawyers, retan in the metropolis—in contact with its statemen, lawyers, physicans, anknows, and the idealigest men and women of wealth physicans, and host physicans, and the physicans, and bologists. It is well that the Frendent of the Royal physician, and biologists. It is well that the Frendent of the Royal meetings of that body? that it senior Secretary abould speed with the physicans of the depth of the depth of the physicans of the onversities? The draft charter of the Athert of inversity does not even attempt to supply such a want. It actually makes the London professor more a creature of competition and the servant of red-tape officialism than he is at this moment. E. RAY LANKESCER.

MR THISELTON DYER has done good service in pointing out the nature of the proposed Albert University, which, unfortunately, seems not unlikely to be the result of the disunfortunately, seems not unlikely to be the result of the dis-cussions that have been going on for the last ax or eight-years with respect to a "Teaching University for London". Should the charter petitioned for by the Councids University and King's Colleges be granted, it will not constitute a reaching University in any real sense, but, as Mr. Tanelton Dyer says, an inattitution very similar to to hat the present University of London of course difficulties of the District Council Course of the Cour of course, differences of organization and machinery, such as the institution of Assemblies of Faculties and Boards of Studies institution of Asembles of Faculties and Boards of Studies (which the estating University ingigit institute next week, if it as difference of principle. The nervest approach to this are the provisions (1) that the Colleges whose institutes are to be eligible as catalidates for degrees shall have a certain amount of representations of the contract o supreat to the Queen in Council (instead of, as in the charter of 1837, being decided on directly by the Crown); (3) that "the University may appoint lecturers independently of a College or medical school to give instruction in any subject, whether it be or be not included in a Faculty."

With the exception of this last provision, slipped in at the end of Section V, "University Digress and Certifi dies," as though modestly shunning the notice that a separate heading might call to it, there is no allusion from beginning to end of the draft charter to any teaching to be done by or through the University as such If it comes into existence, it will be a mere examining University over again. Such a scheme can go no appreciable onversity over again. Such a scheme can go no appreciative way towards remedying the existing defects of University or ganization in London. It is not easy to see what public advantages are likely to result from it. Seeing that it is put forward as representing the views of University College, London, torward as representing the views of University College, London, it does not seem irrelevant to the present stage of the discussion to any that the scheme of the Albert University has never been submitted to a general meeting of the Governori of the College University College, London.

The Cuckoo

I Do not know if the hibernating of swallows and other summer visitors is still a debated question or not, but the following account of a cuckoo may be of interest to some of vour readers

your readers

In the month of August a young cuckoo was taken from its nest and kepl in the house, where it lived and throve—until one day in November, when it escaped and could not be found. But in the following March, during the usual spring cleaning, this very bird was discovered on a shelf in the back kitchen, hidden very bird was discovered on a shelf in the back kitchen, nuagen away behind some old pots and pans, still alive, and salsep, with all its feathers off, and clothed only in down, the feathers bying in a heap round the body. The rude awakening which the cuckoo received was fatal to its existence, for it survived only for a few hours.

Colour-Associations with Numerals, &c.

THE following record of experiments extending over a period of nearly ten years, under exceptionally good conditions, appears of nearly ten years, under exceptionally good condutions, appears to me to be worthy of attention. A preliminary note on the subject was printed in Science, vol. vi. No. 137, 1885, p. 242, part of which is reproduced below.

In 1880, while I was in Washington, I read Mr. F. Galton's note on "Visualized Numerals," in NATURE, vol. XXI p. 352

After I came to Wisconsin—probably late in 1881, or eatily in

After I came to Wisconsin—probably late in 1831, or early in 1832—I mentioned my own entire inability to visualize unnersia or anything else of the kind to a member of the University faculty, Prof Owen I was interested to learn that, when a boy, he had always conceived the vowel sounds as having colour, and that he still retained some traces of this early habit

that he still returned some traces of this early habit

I spoke of this subject in my house shortly after; and my
daughter Midred, then shout seven years old, and she she had
the still be subject to the subject I spoke of this subject in my house shortly after; and m

greenish

greenst. The prevalence of yellow and green, and the scarcity of reds and pinks, are noteworthy. I found that she knew these colours instastly, and when I asked for them in any order. What is more remarkable, she could instantly name the brown letters in a group, the black ones, &c. Apparently she did not require to pass the alphabet in review to decide this. The numbers also had dolours to her, as follows:

had colours to her, as follows:—
1, Mack; 2, cream colour; 3, light blue, 4, brown, 5, while;
6, crimson, pank; 7, greenish; 8, while, 9, greenish (1), 10,
brown; 11, Mack; 12, cream colour, 13, blue, 14, brown; 15,
while; that is, 11 had the same colour as 1, 12 as 2, 13 as 3, &c.
These colour were also named instantly, and in any order,

Erratic Barometric Depression of May 23-29, and Hallstorm of May 24.

Black?

Black or brown

In connection with the very interesting letter of the Rev Clement Ley (on p. 150), descriptive of the barometric depression which passed over these isles towards the end of last month, the following extract from a letter of mine published in the local press, with a view of obtaining frither information, but without success, may be of interest. At the first information, but without success, may be of interest. At the first information, and at of the first information of the first information of great severity and lengthy duration, and at of p.m. the manufacture of great severity and lengthy duration, and at of p.m. the manufacture the ground and roofs of house were covered with a compact layer of frozen rain-drops, which at the end of half as manufact the ground and roofs of house were covered with a compact layer of frozen rain-drops, which at the end of half as the subject of the compact layer of frozen rain-drops, which at the end of half as the subject of the compact layer of frozen rain-drops, which at the end of half as the compact layer of frozen rain-drops, which at the end of half as the compact layer of the lattices, which were carefully all ovarious in form, were smaller than 0.1% by the organization of the period of the compact layer of the lattices, which were careful over use at it. On a Cycle in Weather Changes

It is known that Prof Brueckner, of Berne, in a work on "Klimaschwankungen," published a short time ago, offers a large amount of evidence for the view that our globe is subject to a weather-cycle of about 35 years, a series of cold and wet to a weather-cycle of about 35 years, a series of cold and wet years, or warm and dry ones, recurring at about that merval years, or warm of the control of the control of the control of the his essays (No lvm. "Of Vicissistide of Things"), makes refer to go which I have heard, and I would not have it given over, but wasted popen a little. They say it is observed in the Low but waited spon a nutle. Iney say it is observed in the Low Countries (I know not in what part) that every five and-thirty frosts, great wet, great droughts, warm winters, summers with little heat, and the like, and they call it the prime. It is a thing I do the rather mention, because, computing backwards, I have found the same concurrence." A B. M.

THE FORECAST OF THE INDIAN MONSOON

A FTER an interval of twelve more or less prosperous years, following on the memorable Madras famine of 1876-77, and the drought and fearful mortality of North-Western India in 1877-78, India seems once more to have entered on one of those prolonged series of adverse seasons which put a severe strain on the protective powers of its Government, and, despite all human precaution, bring suffering, disease, and premature death to thousands of its industrious peasants, and to even larger numbers of the impoverished outcasts who form the lowest fringe of its teeming population, fighting the precarious battle of their life at all times on the verge of destitution. The drought in Ganjam in the autumn of 1889 has been followed by the fallure of the late autumnal rains over the central districts of the Carnatic towards the close of last year, and the too familiar machinery of relief works for the able-bodied, and doles of food to the helpless indigent, has been in active operation for several months past in the districts around Madras Another monsoon, another season of those periodical rains on which depends the fate of millions, is now due and overdue, and there comes from India an ominous note of warning that there is reason to fear that more than one great province of the empire, or certain portions of them, may again this year he parched and barren, their young crops withering and shrivelled under the dry west wind,

while, month after month, men scan with ever-growing anxiety the pale dust-obscured sky and scattered ballshaped clouds that never mass themselves to rain-clouds. but mock their hopes with the promise of showers that

And this warning, alas ! is no mere guesswork of credulous and speculative minds, such as in these latitudes certain of our would-be weather prophets love to put forth at hazard, to furnish the topic of a day's gossip to the million, or haply to win for themselves a summer day's reputation with the uninstructed, in the event of a successful issue Certainty, indeed, there is not and cannot be till science shall have extended its domain far beyond its present limits; but, in India, the stately march of the seasons is but little obstructed by the vicissitudes of fugitive cyclones and anticyclones, that originate we know not how, and disappear by some concurrence of causes equally beyond our ken In the tropics, and in the realm of the monsoons, all weather phenomena are more massive and slower in progress, and each great change of seasons is heralded by signs which, if we can as yet but vaguely interpret them, are at least recogniz-able as such, and, with a certain allowance for possible error, must be accepted as timely monitors of what is likely to follow These it is that, whether rightly or wrongly deciphered, furnish the basis for the present warning. To those who, like the present writer, have warning. To those who, like the present writer, have followed for many months past, not without anxious in-terest, the telegraphic and other reports periodically transmitted from India, it comes as no surprise, but as a confirmation of misgiving, long entertained though only committation of missiving song entertaints thought only now backed by the warranty of full official evidence. The events of the next three months may yet belie the present indications, and that they may do so is still our fervent hope, but it would be folly to ignore them, and to shut our eyes to the probabilities that they seem to portend

For the last eight years it has been one of the duties of the Indian Meteorological Department, some time early in June, to prepare, for the information of Government and the public, a forecast of the probable character of the summer monsoon, based on the reports of the snowfall on the Himalaya and the western mountains, and on the indications afforded by the weather of the previous winter and spring. The possibility of framing such a forecast was in a measure foreseen by the Famine Commissioners appointed by the Home Government after the disastrous famines of 1876 and 1877, of which Commission General R Strackey, the true founder of the Meteorological Department of India, was the scientific member : and it is in no small degree due to the weighty advocacy of this Commission that the Department owes its present extension and importance Mr. Eliot's forecast for the coming season is now before us. It sets forth at length the general and special grounds on which he bases his conclusions; and these, though duly guarded by the reminder of their essentially empirical character, and of the unavoidable imperfection of our information regarding certain important data, are expressed in terms that leave unhappily no doubt of the adverse character of the out-

Attention was first directed to the apparent connection of the Himalayan snowfall with the prevalence of dry land winds in India, in the year 1877, and about the same time the late Prof. S. A. Hill and Mr. Douglas Archibald showed that, as a general rule, an unusual cold weather rainfall in Northern India was followed by a deficient rainfall in the ensuing summer monsoon. In a paper published in the Proceedings of the Royal Society in 1884, these two classes of facts were shown to be merely different phases of the same phenomenon, and a summary was given of all the evidence on the subject that had been accumulated up to that date. Since then, there has been but one year of heavy Himalayan snowfall, viz 1885, and in that year the rains were greatly delayed on the Bombay coast, and were very deficient in North-Western India in June, July, and September, commencing late, and terminating early. During the past winter and spring the snowfall on the North-Western Himalaya and the mountains of Afghanistan and Baluchistan has been excessive—indeed, as Mr. Eliot states, unprecedented during the last twenty-five years—and from the reports received from the civil officers and observatories in the received from the critical conservations in the mountain districts, he estimates that an average fall of 40 feet, if not considerably more, must have fallen over all the higher ranges, from Murree eastward to Garbwaj, if not to Central Nepal. That it was the same on the less accessible range of the Hindu Kush we have reason to believe from the casual reports that were received to believe from the casual reports that were received. during the last winter, and we know that in Southern Europe and even in Northern Africa, snow fell down to the sea-level, and was such as has hardly been experienced certainly during the greater part of the present century. The phenomenon has therefore been one of widespread incidence, and indicates some remarkable and rare condition of those higher strata of the atmosphere which, we have now reason to believe, are the seat of the more important changes that regulate the vicissi-tudes of the weather of the globe.

Concurrently with this exceptional extension of the snowfall to low latitudes of the temperate zone, the Indian registers afford evidence of certain abnormal features, which are such as have been noticed on former occasions of unusual snowfall on the North-West Himalava, and the bearing of which on the weakness of the summer monsoon is more clearly traceable In fact, they tend to link the two phenomena together, whether we regard them as the common effects of some more remote agency, or as displaying the different steps of a physical sequence of cause and effect. The most important of these are : the unusual rainfall over the whole of Northern India in the past winter and spring, amounting to from two to three times the average in the Punjab, where it was heavlest, a prevailing low temperature in Northern and especially North-Western India, together with a corresponding excess of temperature in Assam, Burma, and Southern India; and finally, a persistent excess of atmospheric pressure in the former region and a deficharacterized more or less all the months of the present year, especially March and May. As estimated by European standards, the anomalies of this last element may indeed appear small For instance, the mean excess at Peshawar in May was 0 052 inch, at Mooltan 0 041, and at Quetta 0'049 inch, while the deficiency at Calicut was 0'040 inch, and at Sibsagar 0 031 inch. Taken together, they constitute an anomalous gradient from northwest to south and east of something under a tenth of a barometric inch in distances of 1300 and 1500 miles. But in India such differences are relatively large, and, as former experience has abundantly shown, very significant As temporary phenomena they might indeed be of little importance; but, lasting as they have done through mearly half a year, they point to an anomalous state of the atmosphere which is evidently persistent, and is distinctly adverse to the northern incursion of the summer tinctly adverse to the northern incursion of the summer monsoon. Taking the general mean of all parts of the empire, the atmospheric pressure has been above the average in every month of the present year. With respect to the winds, Mr. Eliot remarks:—"South-easterly winds have been unusually prevalent in Bengal and Behar during the months of April and May, and north-westerly and northerly winds on the west coast of india as far south as Cochin. The unusual prevalence of north-westerly winds on the Bombay coast in the month of May was one of the features of the weather in 1876, 1883, and 1885, in which years the monsoon was greatly retarded on that coast."

NO. 1132, VOL. 44

Finally, after reviewing the chief characteristics of other years in which the Himalayan snowfall has been heavier than usual, Mr. Eliot draws the following conclusions with respect to the probable character of the monsoon rains of the present year in the different

provinces of India

"(1) Snowfall conditions on the Western Himalayas. &c., and the pressure conditions in India are very un-favourable to the establishment of a strong and early monsoon on the Bombay coast. It is very probable that it will not be established in full strength on the Bombay coast before the third or fourth week in June, and it is probable that it will be below its average strength, and may be withdrawn from Upper India earlier than usual

in September.

"(2) The snowfall conditions in the Eastern Himalayas. and the pressure conditions in North-Eastern India and Burma, are favourable to the advance of a moderately strong or strong monsoon in the Bay of Bengal earlier than usual, and to its establishment in Burma and Bengal before or about its normal period," and Burma, Bengal, and Assam are expected to receive an average or more than an average rainfall, Behar and the eastern districts of the North-West Provinces about the usual amount In Southern India it is shought probable that the rains may be retarded, but that Malabar and Southern India generally are likely to receive favourable rain during the monsoon.

On the other hand, it is pointed out that "conditions are very unfavourable for Raiputana, and also to some extent in Guzerat, the southern districts of the Puniah. and the western districts of the North-West Provinces. It is probable the rainfall will be more or less deficient over the whole of that area, and possible that the deficiency may be large and serious" In Northern Bombay and Berar it is thought that "the rainfall is more likely to be slightly deficient than up to its normal amount," and that in the Central Provinces it will be "fairly normal

From this abstract it will be seen that the region in which drought is chiefly to be anticipated is the western provinces of Northern India, comprising Raputana, Guze-rat, the southern districts of the Punjab, and the western districts of the North-West Provinces, provinces the average rainfall of which does not exceed between 20 and 30 inches, and which time after time have been the seat of disastrous famines. Now there is one consideration relevant to this subject of which no mention is made in Mr. Eliot's report, and which, notwithstanding that its bearing is purely empirical, cannot, we think, be entirely disregarded when dealing with the question of probabilities. This is the fact, first pointed out by the Famine Commissioners, that between 1782 and 1877, on no less than five occasions, a drought in Southern India was followed by a drought in Northern or rather North-Western India in the succeeding year. It does not seem possible, in the present state of our knowledge, even to suggest any physical explanation of this remarkable sequence, but it has been repeated too often to allow of our regarding it as purely fortuitous, and unfortunately it only tends to strengthen the probability of the adverse conditions inferred by Mr. Eliot from the existing state of things.

It must be confessed, then, that, according to our present means of judgment, the present outlook is by no means hopeful The mere fact of a retardation of the monsoon rains would not in itself afford cause for serious anxiety. According to the latest report from Madras, indeed, this part of Mr. Eliot's forecast seems to have been justified by the event, for on June 26 the Governor of Madras telegraphs that the south-west monsoon rains have not set in properly in the interior, and are very light even on the Malabar coast, whereas the date at which they are

We have taken the liberty of altering the punctuation of this telegram to bring it into accordance with sense and fact.

usually expected is the end of May or the beginning of June. The really critical months in North-Western India in Compense of the Compense o

PHYSICAL SCIENCE FOR ARTISTS!

11

WE next come to the absorption of light 1 do not know whether you have had any opportunity yet in your laboratory course of observing the spectral pheno-mena produced when white light, or say solar light, is absorbed by different substances

The white light is broken up by the dispersion of the prisms into a rain-bow band; while it is possible, by one means or another, one substance or another, to filch out of this coloured hand some of the constituent colours, now at one end. now at another, sometimes in different parts at once; and when this has been done, the light which finally reaches when this has been done, the ught which man, the eye may be of any colour, as is evidenced by the different colours you see in a stained glass window is what happens also by the absorption of our atmosphere, due in all probability in great part to the contained aqueous vapour The sun is white in the middle of the day and red at sunset The blue part of the light, which, when all the colours reach us, looks white, has been taken away, and practically nothing but red is left; only certain parts of the spectrum are left. It is easy, after two or three hours' experiments with the absorption of light by different inedia, to grasp the laws which govern sunset colours precisely as it is easy in the anatomical school to study the facts relating to the human form, particular muscles and the like A diligent student will thus have the world of colour at his feet. This can, however, only be done by one interested in physical science, and I think it should be done by anyone who wishes to deal with landscapes or seascapes, anything, in fact, which has to do with the natural world. The results obtained in this way of course come to us pictorially, chiefly in the colour of sky and water and in the colours of clouds, and they are mixed up in pictures by the knowledge, or want of knowledge, of the artist who paints these various reflecting surfaces. The reflecting surface, whether water or cloud, or what not, mist not only be true in colour, but perfectly formed, in order to give an absolutely perfect and pleasant picture.

Here I think it is that the need of physical scenee is greatest, and I do not know, in fact, that there ought not to be some kind of an examination in a College like this which shall insure that anjone who in going to take up the study of art is not colour-blind. This is done in the case of sations and eignine-drivers, and I think it should be done in the case of artists. There are pictures which have apparently been painted by colour blind people; and much skill has been wasted in consequence of such a much skill has been wasted in consequence of such a malformation as this.

It may be, of course, that in some cases, where the thing may be charttably supposed to arise from a physical defect, it is the result of mere ignorance, or want of observing power; but if that be so, then my point is proved, because it is clear that a good scientific training will cause all the proving the control of the proving the course of the proving the course of the proving the course of the proving the

NO. 1132, VOL. 447

rewarded by the exquisite truth of some of them, that one could very well look over the defects of others, if all thoughts of the possible progress of art achievement

were hanished from one's mind. Some of you may perhaps have read Mr. Ruskin's lapter on clouds The scientific basis of the various chapter on clouds cloud forms, however, you will not find there Now when we consider that in land- and sea-scapes the sky, and especially the clouds, are among the most important re-flectors of light, whether white or coloured, the form of the cloud is absolutely of very high importance If the light is reflected by an absolutely impossible cloud, your delight at the colour, which may be true, is absolutely checked by the treatment of the anatomy of the cloud Here, again, we touch a distinct branch of physical science An acquaintance with the various forms of condensation assumed by aqueous vapour under the various conditions of the atmosphere would certainly keep one right where one would be very apt to go wrong I referred, also, to the reflection of sunlight, whether white or coloured by absorption, by water. Here, I think, is a region where physical science is also helpful There can be no question that the grandest display of colour in the natural world is a sunrise or sunset, either at sea, or where there is a water surface to bring in a second series of re-flection phenomena. As a rule, perhaps, if the water be somewhat land-locked, or at all events not broken up by strong wind, the effect is finer, and this perhaps is one of the reasons, but only one, why the sunsets seen off the west coast of Scotland are so remarkable

This, however, does not always hold 1 have seen a sunne in the Mediterranean when passing the Strats of Gibialiar twenty years ago, which was so magnificent, that not only is it still present in my mind's eye, but all the sulfors who were swabbing the deck at the time ceased work and simply gazed at it entranced. It promised to be a cloudy sunrise, but suddenly the cloud pall melted not mackerel sky, and the sun at rising payed out different colours on the high and low patches, the sea was choppy, and every facet of every wave, and every facet of a facet, being turned to different parts of the sky; these pucked up and reflected to the eye different colours, so

here deep wave looked like a casket of genta.

Ihe red or yellow colours on the clouds depend simply upon the thickness of the atmosphere which the sunlight has traversed for reach them; the colour depends absolutely upon the light received from the sun, and it has nothing to do with the apparent angular distance from the sun in your picture, but while all this change is going on in the clouds the sky itself will be somed above the horizon from the red to the blue overhead, and in addition to that, you will get the gruster humbowy nearest addition to that, you will get the gruster humbowy nearest the control of the colours of th

I have noted a few of those pictures this year, which, in my opinion, and I only give it for what it is worth, are remarkable for their truth, or for the absence of it, in different degrees. The numbers are those of the Royal Academy Catalogue, unless otherwise stated —

Clouds.—Good colour, 311.

Good form, 288, 600.

Good colour and form, 238.

Water.—Good colour, 520, 1029

Good colour, 520, 1029

Good colour, 520, 1039.

New Gallery, 102,

With great deference I must, until convinced to the contrary, hold that much of the colour in the following

pictures is impossible—\$43,1028, 176, 192, 515, it is bad in 203, 498, 586, 602, 1044, 1071.
The cloud forms in 498, 556, and 966 are unlike any-thing I have seen in any quarter of the world.
But cloud is not the only thing we have to deal with.

There is a still finer form of aqueous vapour which shows itself as atmosphere, its function is to soften distant outlines, to gradually assimilate colours, laying, so to speak, its own upon them, and then, again, to soften even this So that distant vistas of hills and vales first become blue in revailing tone, but the most distant ones lose this, and fade to a more neutral tint.

These things this year are admirably rendered in 1130 293 offends by the impossible hardness of the hill on the

right of the picture.

To most of you the terms selective absorption and selective reflection of colour are familiar; of the latter an admirable study is to be found in 1062. For reflection badly managed, study 145 in the New Gallery. The artist seems to be under the impression that some birds have a special capacity for reflecting colour.

Of special studies of various natural objects, I think the following in the German Exhibition are worth examination. a glacier (287), cloudy moonlight (433); careful study of light-grading (but sun should be more

luminous in the latter) (52, 343)

It is not a little singular that we should find such a close association between bad cloud forms and bad colour It was a true instinct which led Mr Ruskin to treat of these matters in his "Mo lern Painters," but why did he not go further into the real basis - the real grit of it all, instead of confining himself to the mere fringe of these great subjects? It was, I expect, because the possible connection between science and art was less recognized then even than it is now. But is it too late? No one could touch the questions still with more sympathy than Mr Ruskin

But to come back to the pictures Almost, if not quite as good as 600, is No 50 in the German Exhibition find in 630 a careful study of colour The most wonderful colour which can be got on nearly still water is that you sometimes see at sunrise or sunset with a good green or yellowish sky near the horizon, and a perfectly blue sky overhead in that case every unit of the surface (every undulation) will reflect to your eye a certain amount of horizon-light and a certain amount of blue sky, and the total result will be a sea of molten steel Another point in this connection se a sea of morten seed a miner point in the connection of this kind from several surfaces besides water. I was in Egypt last winter, and I saw a wonderful sunset, looking out from the little quay at Ismailia. The sand of the

desert lay beyond and round the water in the fore-ground, which was more or less bluish; the lake, in fact, is bounded by sandbanks of no great elevation, the canal coming in at one end and running out at the other In the day-time in full sunshine the sand is yellow, as

vellow as it can be, and at sonset it is grey-white There is nothing very remarkable in the sky, but the intense blue in the sky overhead. There is no aqueous vapour to absorb, and therefore there is no colour But wait for the afterglow! when you get sunlight, reflected from the clouds or sky, which reaches your eye after two transmissions through the lower air ; then you can get colour, and you do get it What you see is the most exquisite violet halo, and the colours with which we are familiar here more or less , but the striking thing is the intense violet halo in the sky, and the warming up of colour till the sunset place is reached. Well, now, what is the effect of that upon the landscape? Everything is turned green, for the simple reason that the only constituent common to the colour which reaches, and is reflected most readily by, the sand, is the tint of green the sands change, as if by magic, into a wonderful chlorophyll green. Now, I venture to think that the artist who endeavours to work out problems of

this kind will be more likely to paint a beautiful picture than the one who copies nature merely, and this brings me into strict harmony with the Academy motto. It seems to me that physical science may in this way, if associated with the study of art, give us new possibilities in the art future that will transcend anything that we know of now, and the time will certainly come, ultimately, when the highest art will result from the study of natural science and the science of the human form.

Seeing that already artists spend years in the study of only one part of the field of observation, they must surely

annex other branches

It would not be right if I concluded what I have to say without calling attention to the important remarks made by Mr Briton Rivière, on science in relation to painting, at the Edinburgh Art Congress

"Whatever may have been done in other lines of human energy during the Victorian age, there can be no question that its most remarkable achievements, both theoretical and practical, have been those of science. The art of the painter has not escaped its influence. one side, and a very important one-that of realism-the side which furnishes the language-re the signs and symbols which express the idea of the artist—there is a wide front open to the influence of science, and on that side art has not been slow or unwilling to follow the advice of science, or ungrateful for the valuable help it has afforded. According to my theory, this supremacy of science would have influenced art under any circumstances, but it has been able to do so through the very method and language of art itself

"Will this influence help or relard the influence of art? My answer is, it may do either, according to the manner in which it is received and used by the artist. If the painter resolutely holds the belief that painting is a language, and a work of art the expression of an idea, and uses science, and all that it has discovered and teaches, to enable him better to understand his signs and symbols, viz the material facts of nature, so that by means of them he may express himself correctly, just as a writer has behind him the philologist to busy himself about the derivation and meaning of words, and the grammarian to show him how to place these words so as to produce the meaning he requires—if, I say, the painter so receives and uses the knowledge and appliances of science, then I think the cause of art will be much advanced by science, and works produced under its influence will be stronger and richer than they could possibly have been without it. On the other hand, if the painter allows this scientific knowledge of the material or realistic part of his work to obscure the purely artistic or ideal part of it, to obscure instead of to intensify the tdea, and if, carried away by the material wonders of the 'thing' which science has unfolded, he forgets the 'thought' altogether, then assuredly, however true he may have shown himself to be to the cause of science, that of art will suffer at his hands-indeed, may be lost altogether For I feel sure that most of my brother artists will agree with me that it is possible for a picture to be scientifically true and have no art at all in it, and, on the other hand, to contain several scientific blunders and yet be a great work of art."

It will be seen, then, that I have ventured to-day to

re will be seen, inche, that I nave ventured to out you preach no new doctrine to you; even my gloss on the Academy motto is endorsed by Mr. Briton Rivière. But I Can go further than this, and quote Prof. Helmboltz in support of the gloss. You should all read his admirable lecture "On the Relation of Optics to Painting". In it he remarks, "The artist cannot transcribe. Nature he must translate her;" and he adds, translation may give us an impression, in the highest " Popular Scientific Lectures," Helmholtz, and Series, p. 135. (Long-mans 1881)

degree distinct and forcible, not merely of the objects themselves, but even of the greatly altered intensities of light under which we view them. . . Thus the imitation of Nature in the picture is at the same time an ennobling of the impression on the senses."

Let me congratulate you on the fact that here, at all events, the importance of physical science in its relation to art is not forgotten. | NORMAN LOCKYER

LUMINOUS CLOUDS

I N an article contributed to NATURE on November 20, 1800 (vol. xltu p. 59), Herr O Jesse (of the Royal Observatory of Berlin) gave an account of the observations of luminous clouds He has retently submitted to the Prussian Royal Academy of Strences a record of later work; and, as the subject is one of considerable interest, it may be worth while to translate his pure?

With regard to the results, already bnefly noted, obtained in the summer of 1890. I have now to ieport more precisely, that with the help of the grint made by the Academy of Sciences we were able, during the period when the phenomenon appeared, to secure a collection of photographs which afford rich material for study

On this as on previous occusions the clouds were visible only between the end of May and the beginning of August They appeared for the first time in 1890, on May 26, for the last time -and then there was only a feeble trace of them—at the beginning of August I he phenomenon, therefore, was seen within nearly four weeks of the summer solstice—before and after it—but cheful after it.

Since my last seport, I have received confirmation of the statement that the time when the plannamenon appears in the southern hemisphere has a corresponding relation to the summer solstice there. Unfortunately, however, more precise facts with regard to place, Sc., in the southern hemisphere, are still lacking.

and sometime the superior of the control of the con

The phenomenon was again less bright than it had been in the preceding year (Tilly when the atmosphere was exceptionally transparent was there an approach to the former brillador. The aggregations of these masses of particles are obviously becoming thinner, as may also be perceived from the more distinct appearance of certain relations of structure, like the ridge and rib formations (wave formations) mentioned in my last report. Formerly these were concealed by superposition goas strata; now the characteristic these of the configurations consisting of these ridge and rib formations present themselves more simply and in greater isolituous.

It has now been proved more successfully than before that the ridges or longitudinal strips lie parallel to, while the ribs or cross strips are almost at right angles to, the direction of the movement of the entire cloud Further, we made on different days several series of measurements

NO. 1132, VOL. 44]

of the distances of the ribs (wave-crests) from one another with the following groups of results:--

Mean	value	of the	distances	of g	wave-crests	Kilom 83
	"	**	.,	10	**	99
	"	,,	**	10	**	8'4
					Average	8 9

1.specially striking, last summer, was the difference between the clearness with which the clouds appeared in the morning hours, and that with which they appeared at the corresponding times before midnight

With regard to the height of the luminous clouds in the summer of 1850 the measurements, so far as they were definitely calculated, gave the mean value of 82 kilom, agreeing almost exactly with the value of nearly 83 kilom, deduced from my photographs of 1880

The persistence from year to year—now for the first time shown with sufficient accuracy—of the distance and therefore of the position of the level surface of the phenomenon, would alone deserve to be recorded as a scientific fact of great importance

Is for the speed and directions of the movements, it was again found that the chief component of the movement was directed from east to west, and amounted to neurity too metres in the second, while the speed of the revolution of the zone of the earth above which the doubt were placed is about 240 metres in the second from west to east

The e was also a smaller and variable component in the direction of the meridian. This was directed from north to south at the times at which we have litherto obtained tolerably secure determinations of movement.

The points of view from which the phenomenon of luminous clouds, on the ground of the observations hitherto made, is to be regarded, are already numerous. There is still, however, a wide field for research in connection with the questions, What are the forces which make the phenomenon appear chiefly in the morning hours? and. What is the nature of those forces which cause the movement of the clouds to be mainly from the north-eist, and drive them from the northern to the southern hemisphere and back again? Then the question as to the lieight of the phenomenon in different latitudes is probably of great importance for the constitution of our atmosphere, and not less interesting is the question relating to the material of which the luminous clouds are composed Unfortunately the interest taken by the scientific world in this remarkable phenomenon is in general so small that during the short time the phenomenon will probably present itself we can scarcely expect to obtain for these questions answers that shall be to any considerable extent satisfactory

WILHELM EDUARD WEBER.

THE venerable physicist, Wilhelm Eduard Weber, whose death on June 23 we shortly announced last seed, was born at Wurtenberg on Copiese 4, and the seed of Posture Divinity at Wittenberg 2. He studied at the University of Halle, where Schwegger was then Professor of Physics, he took his Doctor's degree in 1826, became Provationent in the following year, and Professor-Extraordinary of Physics in 1828. In 1831 he was called to Göttingen to succeed Joinan Tobias Mayer in the Char of Physics, and remained there util 1837. Among other results of the death in this year of King William Lot Charles of Physics, and remained there util 1837. Among other results of the death in this year of King William Lot Charles of Physics, and remained there util 1837. Among other results of the death in this year of King William Lot Charles of Physics, and remained there util 1837. Among other results of the death of this year of King William Lot Charles of Physics, and remained there are the seed of the seed o

[&]quot;Sitzungeber.chte der König'ich Proustischen Akademie der Wisse schaften zu Berlin," 1891. xxvi Si zung der physikalisch-nanhematische Classe, vom så Mar Untersichungen über die sogenannten leuch ende Wolken," von O Jasse, Steglitz.

powers of hereditary rulers. In his view the narrow liberties enjoyed by his subjects, under the Constitution reluctantly granted by William IV. in 1833, were excessive and intolerable. He suspended the Constitution, and thereby called forth vigorous protests from Dahlmann and other Pro-fessors of the Hanoverian University As a punishment, seven of them—Dahlmann, Weber, the two Grimms (Jacob and Wilhelm), Albrecht, Gervinus, and Ewald-were ejected from their chairs, and Gervinus. Dahlmann, and Jacob Grimm were even expelled from the country From this time Weber lived for some years in retirement, but in 1843 he accepted the Professorship of Physics in Leipzig (in succession to Fechner), and in 1849 he returned to his former position in the University of Gottingen He was in Gottingen at the time of his death

Wilhelm Weber's eldest brother, Ernst Heinrich, was the celebrated Professor of Anatomy and Physiology at Leppag He was born at Wittenberg in 1795, and died at Letpag in 1878, having been elected a Foreign Member of the Royal Society of London in 1862. The youngest of the three brothers, Eduard Friedrich, was also highly distinguished as an anatomist, and held office for many

years in the University of Leipzig
Weber's first contribution to science at once took rank weepers arist continuition to science at once took rank as a scientific classic, a position it is likely to keep for many years to come This was "Die Wellenlehre auf Experimente gegrundet." a volume of 574 pages, and 18 copper plates, nearly all engraved by the authors, published in 1835 by the brothers Ernst and Wilhelm Weber, and embodying the results of numberless original experiments and observations One of the most striking results of these investigations was the discovery that, when a regular series of waves follow each other along the surface of water, the particles at the surface describe vertical circles whose plane is parallel to the direction of propagation of the waves, and those lower down ellipses of which the vertical axis becomes smaller and smaller with increasing depth. As to the composition of this work, the authors say that it grew up as the result of such constant and intimate communication between them with regard to all parts, that it is impossible to assign to either of them the separate authorship of any distinct portions.

For several years Weber continued to occupy himself mainly with questions of acoustics, on which he published various papers of importance. In 1833 he published, in conjunction with his brother, Eduard Friedrich, a me-morable investigation into the mechanism of walking

"Mechanik der menschlichen Gehwerkzeuge") "Mechanik der menschichen Gehwerkzeuge")
But it is chiefly by his magnetic and electrical researches that Weber's place in the history of science is
marked These are contained for the most part in the
"Resultate aus den Beobachtungen des magnetischen
Vereins," published by Gauss and Weber from 1837 to
1843, and in Weber's "Elektrodynamische Maassbestummungen" (published in collected form in 1864, though the first paper dates from 1846) In this series of papers
Weber showed for the first time how methods of absolute measurement, analogous to those which Gauss had very shortly before shown to be applicable to magnetic measurements, could be extended into the region of electricity. Before this time Ampère's splendid discoveries as to the laws of the mutual forces between magnets and conductors traversed by electric currents, or between two such conductors, had been made known, and G. S. Ohm had established once for all the relations between electrical resistance, electromotive force, and strength of current; but, nevertheless, there was as yet no settled system for the measurement and statement of electrical quantities themselves. Until Weber's time electrical measurements were merely comparisons be-tween magnitudes of the same kind the resistance of one conductor could be compared with that of a par-ticular piece of wire, the electromotive force of one

battery could be compared with that of another; but that the value of an electrical quantity could be stated without reference to any quantity of the same kind, and in terms not involving any physical constants but the units of length, time, and mass, was as yet an entirely new conception. Weber, however, not only showed that such a system of measurements was theoretically possible, but in a series of most masterly experimental investigations he showed how it could be practically carried out. Our countryman Sir William Thomson was one of the very first men of science to recognize the fundamental character and farreaching importance of Weber's work, and owing mainly to his clear-sighted advocacy of the absolute system of measurement, this system was from the first adopted as the basis for the operations of the British Association Committee on Electrical Standards, appointed originally in 1862. This system has now become so familiar to electricians, and is taken so much as a matter of course, that it requires some mental effort to recall the state of science when it did not exist, and to appreciate the intellectual greatness of the man to whom it is due If we consider method and point of view, rather than acquired results, it is not too much to say that the idea of absolute measurements, underlying as it does the conception of the conservation of energy, constitutes the most characteristic difference between modern physics and the physics of the early part of our century. And to no one man is so large a share in this great step due as to Wilhelm Eduard Weber.

Weber was a Corresponding Member of the Institute of France He was elected a Foreign Member of the G. C. F.

Royal Society in 1850

A SOUVENIR OF FARADAY

THE following letter, written by an old friend of Faraday's and of mine, long since dead, may raraday's and of nune, long since dead, may interest your readers, now that we are celebrating the centenary of Faraday's birth. It came in reply to one in which I asked Mr Ward's assistance in preparing an obstuary notice of Faraday for the Chemical News. WILLIAM CROOKES.

Cornwall, August 30, 1867

DEAR CROOKES,—I should be proud indeed to be the spokesman of the chemical world in doing honour to Faraday's illustrious name on the occasion of his accession. sion to immortality

But I should not dare to meddle with the laurels on so august a brow, without many days and nights of earnest research and meditation, to fit me for summing up, with-out omission, the splendid list of his imperishable labours

Only in this reverential spirit of earnest solicitude to do aright, which is, if I mistake not, the philosophical counterpart of prayer—of the religious feeling—could so solemn a duty be fitly undertaken.

Only with the aid of other minds, kindred with Fara-day's in genius, and filled with the light of his manifold discoveries, could any one man's mind become an adequate mirror to reflect the gigantic Shadow that has just passed to its place in futurity.

For the present it is my fate to fulfil much humbler duties—which, having undertaken, I have no right to set aside For duty must still be done, even when such appeals as yours set the wings of the caged lark trembling, and point him upwards to his barred out home.

I must remain, therefore, a unit among the millions

whose hearts do silent homage to the illustrious dead; and can but watch from afar the starry coronation of which you invite me to be minister.

So best, perhaps. For, after all, the name and fame of

Faraday transcend all pomp of celebration, all burning words of praise. For whose the pen to weave so bright a glory as that electric fire which glows, through all the ages, round his brow, who first drew lightning from the lodestone, as Franklin drew it from the sky?

In the moment of separation that little spark breaks forth—instantaneous yet eternal. It is but one vivid point of the radiance that eneurcles his name, yet of itself it is glory enough.

From that spark a new branch of science has sprung, and under its creator's name, were it mine to carve his

epitaph, these three should be the chosen words :-

FULMEN ERIPUIT FERRO Ever yours faithfully.

F. O. WARD.

NOTES

WE print elsewhere an account of the fourth annual meeting of the National Association for the Promotion of Technical and Secondary Education. After the meeting an important conference was held, and it is now hoped that all the influences which are tending towards the establishment of a proper system of technical instruction in England may soon be thoroughly organized. Next week we shall have something to sav about the work of the conference and about the Association's report

THE conversatione given by the President of the Institution of Electrical Engineers, Prof. Crookes, F.R S and Mrs Crookes, on Monday evening, was brilliantly successful. It was held in the gallertes of the Royal Institute of Painters in Water Colours, Piccadelly. There were about 800 guests, among whom were many eminent men of science

On Tuesday evening the Fellows of the Royal Meteorological Society and their friends dined together at the Holborn Restaurant, to celebrate the entrance of the Society upon its new premises in Great George Street, Westminster Mr B Latham, the President, occupied the chair. Mr A. R. Binnie (Engineer to the I ondon County Council) proposed "The Royal Meteorological Society," and Mr G. J. Symons responded Mr. Latham, replying to the toast of "The President," referred to the enormous amount of records in the possession of the Society. All they now wanted was a few more members However, they had gone on increasing, and were now in a prosperous state, as they had been able to collect from the members of the Society a considerable sum of money, which had been funded, and the interest on which would meet the expenses of the new establishment. The Society now possessed one of the finest meteorological libraries in the world, and one which would be of enormous value to future generations.

WE are glad to note that the Marine Biological Association have now only three unoccupled tables. Many investigators are taking advantage of the facilities offered them at Plymouth

THE Exhibition Committee of the Photographic Society of Great Britain announce that the augual exhibition of that Society will be held at the Gallery of the Royal Society of Painters in Water Colours, Pall Mall East, from Monday, September 28, until Thursday, November 12 next The exhibition will be open daily (Sundays excepted) from 10 a m. to 5 p.m., and on Monday, Wednesday, Thursday, and Saturday evenings from 7 p.m. to 10 pm. Medals will be awarded for artistic, scientific, and technical excellence of photographs, for lantern transparencies, and for apparatus.

THE Pacific Postal Telegraph Company had lately a gathering of some 500 guests at the opening of a new telegraph office

NO. 1132, VOL. 447

in San Francisco. After shortly describing the various instruments, Mr. Storrer, the superintendent, said he was often asked how long it took to telegraph to different places and get a reply He would therefore now send a telegram to Portland, New York, Washington, Scattle, Tacoma, Canso (Nova Scotia), and London, inquiring about the weather The first reply came from Portland in 3 minutes, " Weather fine", the next from New York in 3 minutes to seconds, "Misty and warm" Washington in 3 minutes 11 seconds, "Misty and warm" Seattle in 2 minutes 21 seconds, "Misty and calm", Tacoma in 3 minutes 28 seconds, "Misty, cool, and calm", Canso, Nova Scotia, in 4 minutes 20 seconds, "Cold and misty" while the answer "Misty and cold" came from London in 6 minutes 22 seconds.

THE Governors of the Royal Holloway College have appointed Miss M. W. Robertson to the Resident Lectureship in, Natural Science Miss Robertson, who is now a lecturer on the staff of Alexandra College, Dublin, has taken the degrees o B A and M A, with high honours in chemistry and physics. at the Royal University of Ireland, and has also gained the University Studentship in Experimental Science

THE Education Department has issued a memorandum, by Mr I G Fitch, on the working of the free school system in America, France, and Belgium

Till death of M Rodolphe Kooppelin, a distinguished chemist, is announced. He was born at Colmar in 1810, and from 1828 to 1850 held the Chair of Physics and Natural History at the College of his native town For many years he was intimately connected with the Agricultural Society of the Upper Rhine, and, as a chemist, he was able to render great services to the agriculturists of his department After the Franco-German war, M Koppelin quitted Alsace, and settled in Paris, where he was regarded as one of the most eminent members of the Alsatian colony

In another part of the paper we print a report, by Herr O Jesse, of his observations of luminous clouds in the summer of 1800 We learn from Herr lesse that on the night of June 25-26 last the luminous clouds were again very visible at Sterlitz and Nauen, and that they were photographed eight times simultaneously at these two places. Writing to us from Sunderland on July 1, Mr 1 W Backhouse says there was a fine display of the luminous clouds during the previous night, their motion being, " as usual, from a north-easterly direction Mr I) I. Rowan informs us that on the same night, from 11.30 p m. to 12 30 a m, the clouds, as seen at Kingstown, co. Dublin, "appeared well-developed on a polar arc of 30" and at a mean altitude of 5° " They had been faintly visible at Kings town on June 3, 7, and 9 It is astonishing that no observer seems yet to have had energy and intelligence coough to take spectroscopic photographs of these striking phenomena

ACCORDING to a telegram from Melbourne, dated July 4, the Swedish-Australian Antarctic Committee of the Victorian branch of the Royal Geographical Society, which was formed to raise subscriptions in order to take advantage of Baron Nordenskiold's offer to equip an expedition to the Antarctic regions, announces that a sum of £3000 only is required to complete arrangements, and that there is every prospect of the expedition starting in about fifteen months' time. It is expected that the expedition, in addition to its geographical and other scientific discoveries, will be the means of opening up extensive whale and other fisheries in the Antarctic seas.

WE learn from the Botanical Gasette that Lieut. R E Peary, of the U.S. Navy, proposes to reach the North Pole on foot through Greenland, starting from Whale Sound, and expecting to be absent from It to st years. He states that the region about Whale Sound is rich in Arctic plants. Kane having brought over 106 species of Phanerogams and 42 of Cryptogams, several of which were new, but that very little has been done in its investigation since that time.

THE danger of using argenical preparations for the poisoning of plants is illustrated by the fact that Dr. B. L. Robinson, assistant in the Gray Herbarlum, Cambridge, U.S.A., has been compelled to resign his position owing to ill-health resulting from this cause. It is stated that the poisoning of plants has now been entirely abandoned in the herbarium; the tightness of the cases, and constant handling of the sheets being relied on to preserve the specimens

MR. SPENSER LE MARCHANT MOORE has been appointed botanist to the Matto Grosso Gold and Explorations Concessions Expedition, which is about to depart for Brazil

A NEW botanical journal has just been started, devoted to the diseases of plants, Zeitschrift für Pflanzenkrankheiten. edited by Dr. Sorauer, and published at Stuttgart

DR JOHN MURRAY contributes to the Journal of Botany for July a very interesting account of the Clyde sea area, its physical characters, and the chief features of its natural history This sea-area is a natural system of deep-sea basins or lochs in the west of Scotland, communicating southward with the Irish Channel by a single opening between the Mull of Cantyre and the shores of Wigtown and Ayr It has a water surface of about 12,000 square miles, its greatest depth is 107, and its mean depth about 29 faihoms There is a great variety in the pelagic fauna and flora in the surface and intermediate layers of water, the abundance and the species of organisms varying in the different layers according to the seasons, and even in different years. There is likewise a great variety in the bottomliving fauna and flors, which varies according to the nature and depth of the bottom in the different parts of the area. In some of the deeper lochs a few animals are met with which do not usually occur in more open situations around our coasts till a depth of 200 or 300 fathoms is reached. Some of these forms are limited to one loch on the west coast, for instance, Concharesa elegans, which is abundant in Loch Etive This form has never been taken in any of the lochs of the Clyde sea-area, although Euchata norvegua, with which it is associated in Loch Elive, occurs abundantly in Upper Loch Fyne and Loch Goil Nyctiphanes northerica and Borcophanica Raschie, which are abundant in the upper locks of the Clyde sea area, do not, on the other hand, occur in Loch Elive

THE French Minister of Public Works has addressed a circular letter to eivil engineers, asking them to use their influence to protect prelustoric monuments from the injury often done by ignorant proprietors. It seems that little respect is shown for such monuments in some parts of France La Nature speaks of a proprietor who sold "a magnificent doimen," which was to be transformed into "a tomb in a cemetery"

In his report, for 1890, to the trustees of the Peabody Museum of American Archeology and Ethnology, Prof. F. W. Putnam, the Curator, records that in no former year had the friends of the Institution been so generous in giving aid Gifts for current expenses were received which, in the sum total, exceeded the regular income from the funds, and Mrs Mary Copley Thaw, of Pittsburg, added no less than 30,000 dollars to the amount held in trust, this sum being set apart as an endowment for a fellowship.

An apparatus has been recently constructed by M Ducretet, NO. 1132, VOL. 44]

80° C. below zero, by means of the expansion of liquid carbonic acid. The inner of two concentric vessels contains, in alcohol, a serpentine metallic tube communicating through a tube with two stopcocks, with the carbonic acid reservoir outside, and opening below into the annular space round the inner vessel, in which are some pieces of sponge impregnated with alcohol-This two-walled vessel with coil is inclosed in a box. One stopcock being opened wide, the other slightly, the carbonic acid passes through the coil as snow, and turns to gas, with strong cooling effect, and sny of it not vaporized in the coll is dissolved in the alcohol of the sponge. The gas escapes through a tube passing through the outer box. The instrument, called a cryogen, is represented in Cosmos of June 27.

EXPERIMENTS have lately been made by Herr Regel (Bot. Centralb.) with reference to the influence of external factors on the smell of plants. In the front rank appears the direct and indirect influence of light on the formation of etheric oils and their evaporation. In the case of strongly fragrant flowers (as Reseda) heat and light intensify the fragrance, which in darkness is lessened without quite disappearing. When the whole plant was darkened, those huds only which were before pretty well developed yielded fragrant flowers; the others were scentlets If, however, only the flowers were darkened, all were fragrant. Other plants open their flowers and smell only by night (as Nicotiana longiflora and Nyclerinia copensis) When these plants were kept continuously in the dark, they, in course of time, lost their scent, as they lost their starch. On being brought into light again, both starch and fragrance returned, Besides light, respiration has a decided influence on the Nycterinia, inclosed in a bell iar with oxygen, behaved normally, but with hydrogen the flowers did not open, and had no fragrance. In general, the opening of flowers coincides with their fragrance, but there is no necessary connection between these phenomena

A NEW antiseptic, said to have certain advantages over those hitherto in use, has been brought before the French Academy of Medicine by Prof Berlioz, of Grenoble, extreme solubility, harmlessness, efficacy, and rapidity of action are claimed for it. It is called microcidine, and is a compound of naphtol and sods, is neither poisonous nor irritant, is twenty times as active aborse acid, and much more soluble than thymol, carbolic acid, &c Microcidine has the form of a greyish-white powder a solution of 3 grammes per litre it is very slightly coloured, but it does not stain either the hands or bandages For family use it is said to be of great service

MOST Russian geologists are now of opinion that the boulderclay which covers the whole of Middle Russia is nothing but the bottom moraine of the ice-cap which, during the Glacial epoch, extended from Scandinavia and Finland to the latitude of Kieft and Poltava A couple of years ago, Prof. Pavloff, while working in connection with the Geological Survey in Nijni Novgorod, indicated some traces of an inter-glacial milder period among the glacial deposits covering the province. Like indications have been noticed in Poltava and Tchernigoff New data to confirm this view are now given by N. Krischtasovitch in the Bulleten of the Moscow Naturalists (1890, No 4). After a careful exploration of the Quaternary deposits at Troitzkoye---a village on the Moskva River, seven miles to the west of Moscow, the diluvial deposits of which have very often been mentioned since Prof. Rouillier's and Murchison's times-the Russian geologist came to the conclusion that these deposits are indicative of an inter glacial period, during which Middle Russia had a flora and fauna much like those which exist now, but with the addition of the Mammoth The layers described by M. Kraschtafovitch as inter-glacial are of lacustrane origin; they for getting quickly in the laboratory a fall of temperature 70° to are covered with undoubtedly glacial deposits, and they are

deposited over glacial sands containing boulders of northern origin. Further research, however, is wanted. It is certain that, both during the first invasion of the ice-cap and its ultimate retreat, its outer limits must have been subject to very great oscillations. We know that, in Greenland, parts of valleys which for hundreds of years were covered with vegetation, are sometimes invaded again with ice, and that lacustrine deposits must arise in this way between purely moranic deposits same must have taken place in the Ice-cap of Russia; and the oscillations of the glaciers on the outer border of a large icecap are on on a much greater scale than the oscillations of isolated glaciers in Aloine regions. When the ice-can began to invade Middle Russia, its advance was undoubtedly accompanied by many oscillations : regions invaded by see must have been set free of lee for a succession of years, and they became the seats of lakes. The same oscillations must have taken place during the retreat of the ice-cap. The existence of a warmer inter-glacial period, therefore, though not improbable in itself, can be proved only by means of a very wide exploration of the boulder-clay, and such an exploration has not yet been made

This system of meteorological observation in Alisace-Lorrane has now been centrilised, a neteorological servee for the Reichland having been established. The control of the new service has been instructed to the geographical remarks in connection with the Strasburg University, and has been definitely understood the strasburg University, and has been definitely understood that the strasburg University, and has been definitely understood that the strasburg University, and has been definitely understood that the strasburg University of the Strasburg Universit

A REMARKABLE series of three hailstorms which passed over Graz on August 21 last year, about 5, 6, and 7 pm re spectively, has been carefully studied by Prof Prohaska (Met. Zeits.) Stones from 1 6 to 2 4 inches in diameter fell in the town, forming a compact ice-mass, in some places about 3 feet thick, and a white cloud of vapour formed over the ice. It is noteworthy that all three storms took a nearly quite straight path over mountain, valley, and plain, no influence of mountain, on the direction was perc public. The advancing strips of hail were 10 to 14 km in width , the first went 173 km east-south east , the second and third almost exactly east, one 110 km , the other 201 km The 70 km stretch of country from Stiwoll over Graz to the Hungarian border lay in the path of all three, so the ice deposited by the first offered no hindrance to the others, Mountains seem to have affected the velocity, if not the direction, of the storms, they were passed more slowly than plains or undulating ground (35 km, an hour against 49 km) A violent wind came out from the hail column, a west or northwest wind in front, north on the south side But further out, in front especially, there was a well-marked air current towards the hadstorm, and this was especially sirong on the lee side of a mountain. Whirling movements were not observed, and there was but little thunder and lightning The falls of temperature were very pronounced : eg in the first storm from 26° C to 5°. The barometer went down before each hailstorm, then suddenly

AT the meeting of the Linnean Society of New South Wales on May 27, Mr. Hearty Dease stated that in April, while traveling by sight through the Big Soreb in the Richmond River Daviet, his literate was aroused by the remarkable effect produced by luminous useens which abounded by the rounded driver in the meeting the state of Ceruptana meeting, Sk, which are also phosphorescent, Mr. Fletcher, who had seen the precincular formstade, was of the opinion that these were very repetitions formstade, was of the opinion that these were very

probably also dipterous larve. Mr. David made some remarks on certain luminous organisms which he had observed in old coalmine workings in Illawarra, the Identification of which it was hoped would not long be postponed.

MESSES. CASSELL AND CO. have usued Part 33 of the "New Popular Educator," which is to be completed in forty-eight parts. The present number includes, besides the illustrations in the text, a coloured representation of insectivorous plants.

THE first volume of Messrs. Whittaker's new "Library of Popular Science" will be an elementry introduction to astronomy, by Mr G. F. Chambers. The volume will be ready in the course of a few weeks, and will shortly be followed by others.

An interesting report, by Mr Campbell, of the British Consular Service in China, has been issued by the Foreign Office It is the record of a journey of over 1300 miles in districts in Northern Corea, many of which have never before been visited by Europeans Mr Campbell started from Seoul, the capital, and crossed the peninsula to the treaty port of Won-san (Gensan). and thence pursued his way along the east coast around Broughton Bay, whence he turned north-eastward, crossing the Yalu River to Park tu-San, known to Europeans as the Long White Mountain, and already visited by Messra James, Fulford, and Younghusband The return journey was partly over the same ground, but on arriving at Won san Mr Campbell recrossed the peninsula, and so made his way to Seoul Besides the ordinary record of this journey Mr Campbell gives a great amount of information on various subjects connected with Corea. The chief amongst these is a most interesting section on the prevalence of Buddhism in the pennisula, and one on the agriculture and productions He gives a good deal of information in regard to the geography of Northern Corea, and also of the gold production of the country That Corea contains gold-bearing strata has long been known through the export of gold dust from the ports, but from Mr Campbell's report it appears that gold-fields do exist in considerable numbers, and that some of them are worked with the imperfect native methods doubt that, if circumstances were favourable to the proper scientific working of the Corean gold-fields, the country would be one of the principal producers of the precious metal in the world Education in the country seems to be at a very low ebb, and is confined to a knowledge of Chinese All energy and enterprise is crushed out by an all-pervading tyrannical officialism, and poverty and squalor are universal

THE new reports of the Inspectors of Sea Fisheries are interesting chiefly for the observations of Mr Fryer on the oysler fisheries. He mention the appearance of a curious disease in the neighbourhood of the Thames estuary. in the course of which the shells become so rotten that they will not bear the pressure necessary to open them. The oysters themselves were in good condition, but their round shel's, which were muddy, were completely tunnelled in all directions, while the flat valves, which were clean, were unimured. This points to the conclusion that the ravages were caused by some enemy working from below. The borings were not, Mr. Fryer says, those of either Cliona or whelk-tingle, and it seemed probable that they were the work of a minute Annelid which was present in abundance in the interstices of the shells, and in the adherent mud. In a further example sent to him in June no worms were present, although the oyster-shells were similarly undermined; but their place was taken by larve closely resembling, if not identical with, those of the worm Polylora ciliata A means of guarding against its ravages, suggested by Mr Fryer, is the use of an apparatus recently invented by M Bouchon Brandely, and employed in some of the French oyster earcs for the pur-

pose of facilitating the growth of oysters. This consists of a series of shallow flat baskets or trays of wire-netting on an Iron frame, about 4 inches deep and 2 feet square, placed in tiers. and held together by two iron bands, the number depending on the depth of water in each case. These are either fixed to the soil, or suspended from rafts or other floating bodles, by which means depths of water otherwise inaccessible can be utilized. The other advantages claimed for the apparatus are economy of space in "planting" oysters, and of labour in collecting them. protection of the ovsters from five-fingers, and from contact with unsuitable soil, and their exposure on all sides to the free circulation of the water, resulting in more rapid and regular growth, and a greater tendency to depth of shell than under the most favourable of ordinary circumstances. In the case of beds infested with the boring worm referred to, the trave in question would in all probability afford a ready means of placing the ovsters beyond the reach of these marauders. The convenience of such appliances, especially in cases where French ovsters are laid down temporarily on English beds, to be afterwards transferred to other grounds, e.g during the winter, would probably be found to be very great,

Ar a meeting of the Chemical Society held on June 18, a paper was read by Ludwig Mond and F Quincke, on a volatile compound of iron and carbonic oxide. The authors describe experiments from which they conclude that iron forms a volatile compound with carbonic oxide of the formula Fe(CO), corresponding to that of nickel Very finely divided iron-obtained by reducing iron oxalate by hydrogen at a temperature but little exceeding 400°, and allowing it to cool to 80° in hydrogen - when heated in an atmosphere of carbonic oxide gave a gas which burnt with a yellow flame, and on passing the gas through a heated tube a mirror of iron was formed at between 200° and 380°, while at higher temperatures black flakes of iron and carbon were deposited. Only about 2 grams of iron, however. were volatilized after six weeks' treatment of 12 grams of the metal: it was necessary every five or six hours to interrupt the operation, and to re-heat the iron to 400° in hydrogen during about twenty minutes. When passing carbonic oxide at the rate of about 21 litres per hour, not more thin o of gram of iron was volatilized, corresponding to less than 2 c c. of the compound Fe(CO), in a litre of gas. The authors have effected an analysis of the compound by passing the mixture of gases into mineral oil, boiling between 250" and 300", and heating the solution so obtained to 180°, 1ron free from carbon is then deposited and carbonic oxide gas is evolved Five analyses are quoted, the results of which give a ratio of Fe CO, varying only from I 403 to 1 . 4 264. Dr Armstrong said that the authors' discovery was extremely interesting on account of the explanation which it might be held to afford of the permeability of iron by carbonic oxide at high temperatures, as well as to the production of steel by the cementation process, to which Graham had drawn special attention. Just as platinum was permeable by hydrogen and silver by oxygen at high temperatures, so iron was permeable by carbonle oxide, it might be supposed, in each case, because a dissoclable compound of the metal with the gas was formed. Prof Thorpe drew attention to the value of the experiments in connection with the production of steel by the cementation process. and stated that he had recently observed that platinum had the property of causing the separation of carbon from carbonic oxide. Mr. Mond said they had refrained from discussing the application of their discovery in the directions indicated, as the compound was only obtained at low temperatures. Dr. Armstrong said this might well be the case , but as Mr. Mond and Dr. Quincke had established the all-important fact that iron had a specific affinlty for carbonic oxide, the argument he had used would apply, although the compound might not be sufficiently stable at high temperatures to exist alone.

NO. 1132, VOL. 44]

THE additions to the Zoological Society's Gardens during the past week include a Chimpansee (Anthropopithe us tregledyles &) from West Africa, presented by Major Al. McDonnell Moore: a Duyker Bok (Cephalophus mergens &) from South Africa. presented by Mr A. Barsdorf, five West Indian Ascortis (Dusyprocta antillensis) from Jamalca, presented by the of Governors of the Institute of Jamaica; a Spotted Cary (Calogenys paca) from Guiana, presented by Mr. R. Kirk; two Slow Lons (Nycticebus tardigradus), a Javan Fish-Owl (Retute javanensis) from Java, presented by Mr. R. Dixon : an Oran cheeked Waxbill (Astrelda meltoda), a Zebra Waxbill (Estrelda subflara) from West Africa, a Nutmeg Finch (Munia punctularge) from India, presented by Mrs. Harris . a Chattering Lore (Lorsus garrulus) from Moluccas, presented by Miss Allce Dundas , a Common Viper (Vipera berus), British, presented by Mr W. H. B. Pain , four Grey Parrots (Pisttacus erithacus) from East Africa, deposited : a Thar (Capra semiasca), born in the Gardene

LORD HARTINGTON ON TECHNICAL EDUCATION.

THE fourth annual meeting of the National Association for the Promotion of Technical and Secondary Education took place on Friday last at 14 Dean's Yard, Westimister Lard Hartington, President of the Association, occupied the chair. He said:—

In opening the proceedings it will be, fortunately, unnecessary for me to trouble you with more than a very few brief observations. It has not been considered necessary to make any attempts to obtain a very large attendance to day, or to meet in any place where we could have a meeting on the scale of others which we have had on this subject in previous years, not but that we have arrived at a very important epoch in the development of the objects for which this Association was founded lopment of the objects for which this Association was sounced four or five years ago. It may, perhaps, be desirable for me, in the first place, to call your attention and the attention of the public to the special objects for which this Association has been founded, as I think there is in some quarters some missapperhension as to the practical nature of the objects which we have in view. As is stated in the report, its object has not been to interfere with the teaching of trades in workshops, or with the industrial and commercial training in the manufactory and in the warehouse. It desires, first of all, to develop increased general dexterity of hand and eye among the young, which may be especially useful to those who have to earn their own lively hood, and at the same time improve rather than huider their general education, secondly, to bring about more widespread and thorough knowledge of those principles of art and science which underlie much of the industrial work of the nation , and, thirdly, to encourage better secondary instruction generally, will include more effective teaching of foreign languages and science, for those who have to guide our commercial relations abroad and to develop our interests at home. Now, those are the objects to carry out which this Association was founded. At the time when it was first originated, these objects were very little recognized in any quarter. They were not recognized as in any degree the duties of the State, except to a very limited extent, so far as the opera-tions of the Science and Art Department were concerned But, useful and valuable as has been the teaching carried on under the guidance and direction of the Science and Art Department up to a very short time ago, I think it may be said that scarcely any attempt had been made to give to that teaching a practical application, or to apply its instruction to the advancement and improvement of the industries of the country. Well, the absence of any State recognition was not to any large extent sup-lied at that time by private efforts. It is quite true that a few manu-facturers in different parts of the country had set the very useful example of establishing, in connection with their works, some technical and scientific teaching. There were also a few institutions, such as the well known Polytechnic Institution for the City and in various other parts of the country, which were making attempts to give instruction with the objects which were making attempts to give instruction with ine objects which I have just enumerated, but those efforts were rather of a philanthropic than of a practical character, and they had not lorur of five years ago attained a very large or extensive development. Well, we may look back now at those years as years of very great and very satisfactory progress. I will not say all that years are proposed to the proposed of the prop has been done has been done in consequence of the exertions of this Association Certainly these objects have been greatly advanced since the foundation of the Association, and, we flatter conrelves, to a certain extent in consequence, of the efforts of the Association But whether the progress that has been made has been in consequence of, or independent of, any exertion of ours, it is equally a matter of compratition that progress has been made. In the first place, those objects to which I have already to the control of the progress ourselves, to a certain extent in consequence of the efforts of the principle was for the first time admitted; but a very much greater step was taken in the next year, 1890, when, under the Local Taxtion Act, a sum very nearly approaching £750,000 for England and Wales was placed at the disposal of local authorities, mannly for the objects which this Association of the sum has moved. It is quite true that the application of that sum power of local authorities in whose hands it with placed to apply it in aid of the race or to other purposes, but the efforts of the Association were directed, as I think I shall be able to show you, with very great success, in order to secure the appropriation of these large funds to the purposes of practical technical instruction. You will recollect that in the winter of last year—I struction. You will recollect that in the winter of last year—I think in December—an important conference was held under the direction of the Executive Committee of this Association at the rooms of the Society of Arts, in which members representing County Councils in various parts of the country entered lato conference and discussion with the Executive Com-

mittee of this Association. Information was given as to what had already been done by certain County Councils which had taken the lead, and suggestions were made as to the manner in which other Councils could most usefully follow their steps and devote these sums to the purposes for which we believe they were intended by Parliament. The results which have already been accomplished are recorded in the ort of this Association, which will be immediately circulated Of County Councils in England, excluding Monmouthshire, 37 Of Courty Councils in England, excluding Monmouthabite, 37 have already decided to give the whole of this grain for the purposes of technical instruction. S have decided to give a part of the purposes of technical instruction. S have decided to give a part of the same purpose, and 2 only have decided to apply the whole of it in aid of the rates. In Wales and Monmouthabite it County Councils have, given the whole to the county for the part of the wales of the county for the first part of the wales of the county for the first part of the first part of the county for the first part of the first p funds to educational purposes, and 3 have devoted a part to the same objects. In Wales 2 county boroughs have devoted the whole of the fund to education, and none to any other purposes. With regard to 23 county boroughs, either we have not sufficient want regard to 23 county boroughs, either we have not sufficient information, or they have not yet arrived at a conclusion apon the subject. Well, that appears to us to be an extremely encouraging result so far as it has gone. The exertions of the Exercise Committee have not, however, been entirely confined to securing this appropriation of the funds placed at the disposal of the Countils by Parliament. The same genitemen who have taken the least in the matter from the beginning—I refer chiefly to my friend Sir Henry Roscoe, Mr Acland, Mr. Hobhouse, and others—have obtained from l'arliainent additional legislation considerably extending and developing the principle which for the first time received the assent of Parliament in 1880. think it is hardly necessary that I should give further informa-tion as to the effect of the amending Act of this session tion as to the effect of the amending Act of this session j prefer to leave the guiltenen I have named to give that ex-planation. But I desire, however, to point out that the work of this Awocation, which has been so uccessfully begun, has not by any means yet ended. The application of these grants in the various localities; to Gourse, a work of great variety and of the utmost importance Fortunately, I think, the State has not undertaken, except under very wide conditions, to exercise any supervision over the application of these funds. In a country prosessing industries of so extremely varied a cha Country possessing industries of so extended varieties where a racter as our, it would have been amost undestrable, and I think certainly would have been most undestrable, that any cut and dried system should be ad pted by which one identical, application of public money to purposes of technical instruction should be adopted all over the country. The applimentation smouto ne acopten an over the country. The appli-eation of these funds must vary very greatly in agnetitural districts, and in agricultural districts themselves as between arable and dairy or cheevemaking districts It must vary in those districts which are chiefly devoted to cotton and woollen modulture, and those substantials. industries, and those which are chiefly employed in the coalmining, metal, or chemical trades, and in almost every different mining, metal, or chemical trades, and in almost every different county of England a different application of those resources would have been required. I think very wide discretion has been very wisely left by Parlament to the local authorities themselves, which are in this instance County Councils or county. borough councils. And these Councils have again adopted the wise course of appointing committees to prepare schemes for the approval of the Councils for the application of these grants. he work was, of course, very new to a great many who had to take it up, and this Association has been able, we think, to give valuable assistance to them, both by affording information and valuable assistance to them, both by anothing into mattol and giving advice, and, above all, by providing the means of com-munication between those who are interesting themselves in this work in various parts of the country, to enable them to know what other authorities were doing, what difficulties were found, what means had been found of surmounting those difficulties, and of generally taking counsel and acting together in eo opera-tion Now, the subject of agricultural education, which up to a very short time ago had been almost entirely neglected, has been by many Coniny Councils vigorously taken up. Couries of instruction in elementary science applying to agricultural pursuits have been instituted, and sho instruction of a still anote precised character, in the slope council process of the still anote process of the still anote that the still anote of the still anote that the still anote t has been by many County Councils vigorously taken up. Courses

the desire of the County Councils to Improve the agricultural educa-tion of their districts will be provided. I am glad to say also that the Important subject of the technical education of girls as well as boys is receiving almost universal attention from County Councils Suggestions have been made by this Association, which have in Suggestions have been maje by this Ausociation, which have in most cases received attention, to privide not only for the in-struction of the boys, but also of the girk, in such subjects as cookery, laundly-work, and dary management. In all these matters the Association has been able to give some substance, and the third with their remains a great deal still in which they will be able to afford the same nature and description of they will be able to afford the same nature and description of assistance I need not say, ladies and gendlemen, that for a very considerable time the work which is likely to be thrown upon that Association will be work which cannot be conducted without considerable financial resources. The income of the Association is not a very large one. We have made an appeal Association is not a very large one. We have made an appeal to many of those who throughout the country have literested themselves in this work in connection with County Councils, and we have received very liberal assistance. I think, however, the time has come when we may hope that the efforts which have been made will be to a certain extent, still more than they have been made will be to a certain extent, still more tank ney have higherto been supplemented by the assistance of gentlemen connected with the great manufacturing, mining, and commercial industries of the country, who are likely, I think, to derive at least as much benefit from the operations of this Association, least as much benefit from the operations of this Association, and from the development which it has aided in giving technical instruction throughout the country, as the agricultural industry has already received. Ladies and gentlemen, I must apologue to you for the imperfect character of these observations, which I have been obliged to condense as much as possible, as my time, and I date say yours, is extremely hmited I only hope that any omissions which I have made will be supplied by my

friends who are on each side of me Sir H. Roscoe, M.P., presented the report of the work of the Association during the past year He said that there was no doubt that during the year a very great expansion of the work of the Association had been seen under both the Acts of Parfiament to which reference had been made by the Chairman The spread of technical education throughout the country had been most remarkable. From what had already been said by been most remarkable. From wan an arrestly been said by Lord Hartington, it would be concluded that practically the whole of England had devoted the whole of the money to technical instruction. The effects of this could scarcely be over-estimated The only two places where the money had been devoted to the relief of the rates were, he regretted to say, London and Middlesex. But it should be borne in mind that what had been already accomplished was nothing to what re-mained to be done. The County Councils were as yet only breaking the ground. Their efforts were merely tentative They had, as it were, to work out their own salvation in this They had, as it were, to work out their own salvainon in this matter of elicitation, and there was certain to be at no great matter of elicitation. The state of the salvaint Shire had been able to vote money to assist the Yorkshire College in its scheme for the improvement of agricultural education Many of the County Councils had already appointed caucasion army of the County Councils had already appointed organizing secretaries, and twas on these that the main part of the work would fall. To them they had to look for the special organization of each particular district, and the importance of their work could scarcely be overrated. Then in the county of the county o their work could soarcely be overrated. Then in the county broughts the work was foring got into shape. In Sheffield a sum of £8495 had been appropriated towards assisting instan-tions groug technical and secondary education. In the same way in Manchester £10,000 had here devoted to a like purpose Agrenitural electration was making rapid progress, and already the standard of the same properties of the same properties of the same properties of the same properties of the same high client springly the same properties of the same properties of 90 some part of the money being devoted to be technical inof some part of the money being devoted to the technical in-struction of girls, he concluded by expressing the hope that the Association would be placed in a position by an increase of its resources to carry on actively a work that was daily becoming

on the motion of Mr. H. Hobhouse, M P., seconded by Lord Thring, the report was unanimously adopted

Lord Hartington at this point left the chair, which was taken

adds, recently committee, and efficers of the Association, the second of St. 1900 and 1900 an

work until the country is provided with an organized system of secondary and technical education."

Miss Hadland seconded the resolution, which was agreed to, seconded, a vote of thanks to the Charman, and this having to a vote of thanks to the Charman, and this having been hearthly accorded was acknowledged by Sir Bernhard Semuelson.

The proceedings then terminated.

SCIENTIFIC SERIALS.

In the Journal of Bolasy for May, Prof R J Harvey Gibson has an interesting article, illustrated, on the histology of Polysyshowns distinguist in the June number, Mr. A. W Bennett contributes a short paper on excasility aways the Conjugate These numbers also contain continuations of Mr. E G. Baler's synopsis of the genera and species of Malvex, and of the Rev H G Jameson's useful key to the genera and species. of British mosses.

THE papers in the Botanical Gazet's for April and May are concerned almost exclusively with American botany Mr. D. M. Mottier has an interesting note on the apical growth of Hepitice, which bears such a striking resemblance to that of the prothallium of ferns.

THE number of the Nuovo Ginnile Rolance Italians for April is chiefly occupied by papers of special interest to Italian hotanists, and by the Bulletin of the Italian Botanical Society Among the articles coming under the latter head is one by Sig Baccarni on the secretory system of the Papilionace, and one by Sig Pichi containing an account of experiments on the parasitism of Peronospora on the vinc

THE Botanual Magazine of Fokyo still contains occasional articles to the English language. Those in the numbers most recently received, for March and April, relate to the native plants of Japan.

SOCIETIES AND ACADEMIES. LONDON,

Royal Society, June 11 — "A Study of the Planté Lead—Sulphuric Acid—Lead Peroxide Cell, from a Chemical Standpoint. Part 1" By G H Robertson. Communicated by Prof. Armstrong, F.R. S

The investigation, the results of which are recorded in this paper, was instituted about a year ago at the Central Institution, at Dr. Armstrong's suggestion, as McLeod's observations on the electrolysis of sulphune acid solutions led to the supposition

the electrolysis of sulphane acid solutions led to the supposition that the changes occurring in the acid were probably less simple than was commonly supposed. This supposition was verified. The first extent of the paper deals with the nature of the lead salt formed during discharge. Experiments made on various samples of red lead of different percentage composition showed that, as with nitne, so with sulphuric acid, it behaved

showed that, as with inter, so with sulphure acid, it behaved the a mature of percide and monoutie, the valphure formed always corresponding to the monoude originally present. As analysis allone can give no proof of the existence of a definite homogeneous sulphate corresponding to red lead, reduces must be obtained that the product different is some of the properties from a military of the product different process that the product of the properties of the product different process that the mixture of sulphage and overcords and have some admired sulphage. E.M.F. of an oxysuipnate would filter from a corresponding mixture of sulphate and personde, and have some definite value, but experiments made with mixtures of sulphate and peroxide in different proportions, and with the product obtained by treating red lead with dilute sulphuric acid, showed that there was a difference of degree only between the red lead pastes and the mixtures.

With regard to Frankland's observations respecting the

colour of the product formed on the peroxide plate during discharge, and the reducibility of the sulphate, the author points out that the colour is due to the incomplete reduction of the peroxide; and that careful examination of the plugs from or the perusaue; and that careful examination of the plugs from a duscharged cell shows that the base consists of practically unlicered peroxide of lead, and that the surface, which is rich in PbSO_a is really a mass of partially reduced granules of peroxide of lead which are coated with sulphate

or team which are coated with supprate a very difficult to reduce, it is well known that mixtures of lead sulphate and peroxide of lead, or other conducting substances, are reduced with comparative case, and that it is very minimate mixtures of this nature

which have to be dealt with as a rule in charging a cell In conclusion, the author points out-

In conclusion, the author points out—

for conclusion, the author points out—

for That neither chemical not electrical test give any ground for

the conclusion of the conclusion of the conclusion of the conclusion

to concerned in the unreaction occurring in the cell.

That were the sadden lowering of the E MF, caused by a

change in the nature of the chemic-! compounds formed on the

plates, it is very difficult to account, for the very rapid recovery

of the E M.F exhibited by an apparently discharged cell.
In the second section the electrolyte is dealt with, and, after referring to the work of Berthelot, Richarz, Schone, Traube, and others on the electrolysis of sulphuric acid solutions, the author outers on the electrolysis of sulphuric acid solutions, the author describes experiments made to test the effect of the addition of sodium sulphate to the electrolyte, as recommended by Mr Barbour Starkey, as it seemed probable it had a catalytic action on the "peroxides" always found in electrolyzed acid of the strength used in batteries

Mr. Preece most kindly aided the investigation by allowing experiments to be carried out at the General Post Office, where experiments to be carried out at the General Post Office, where one-half of the secondary cells, contain 1 per cent of sodium sulphate, and the other half ordinary dilute acid, sp. gr. 180 it was found that the addition of sodium sulphate in about the proportion of 1 per cent to freshly electrolyzed, acid, or during electrolyzed, wasys produced a diminuation in the total quantity of "active oxygen," and brought the amount present in the plain cells down almost exactly to that found in the volume sulphate

Determinations were made of the amounts of "active oxygen present as persulphuric acid and hydrogen dioxide respectively, and it was established that acid taken from the cell reduced peroxide of lead. The presence of hydrogen dioxide being thus peroxide of fead. In the presence of hydrogen dioxide being thus catabilished both directly and indirectly, its effect on the L M F of a cell was tested. It was found that, while the addition to the acid in the case of a lead head-peroxide couple in idiate sulphuric acid produced an annulment, or reversal, of the L M F, the introduction of hydrogen dioxide into the body of the peroxide paste produced an increase in the E M F in the case of a platinum lead peroxide couple.

The Post Office records showed that, while the general cha-

racter of the temperature and specific gravity changes occurring during charge and discharge were the same in both types of cell, there was less sulphating with the sodium sulphate elec-

trolyte. The cause of the pink colour of the acid, noticed by Mr.
Crompton and others, was investigated, and found to be per-manganic acid, formed probably from the manganese present in commercial lead

commercial tead
In conclusion, the author points out—
That peroxides are found in appreciable quantities in the
electrolyte during charge and discharge;
That their influence aust not be neglected in considering the

behaviour of the Planté cell ; And that it is to the electrolyte, rather than to the plates, that attention must be directed if any considerable improvement is to be effected.

"Part II.-A Discussion of the Chemical Changes occurring in the Cell," By H. E. Armstrong, F.R.S. and G. H. By H. L Armstrong, F.R.S. and G. H.

The authors arrive in this paper at the following conclusions The subors arrive in this paper at the following conclusions— (1) That the cooling observed in the Plantic cell can only be explained as resulting from the dissociation of the dilute sul-strainty, and Woods are in practical agreement with those calcu-lated on the assumption that the acid used is sulphure acid listed, H₃SO₄, that in all probability such acid, and not the dilute acid contained in the cell, is operative throughout. (2) That the observed loss to efficiency cannot be due to tem-

perature changes, as these arise through actions occurring out of

circuit (3) That it is difficult, from a comparison of calculated with observed values of the L M F, to arrive at any find conclusion as to the exact nature of the changes which take place in the cell. On the assumption that sulphating occurs at hoth plates in circuit, and under the influence of IL₂SO₄, the calculated value is considerably too high, while, it sulphating occur only

value is considerably too high, while, it sulphating occar only at the lead plate, the value calculated is far too lovel (4). That a counter E. M.F. of about 0.5 voit would account for the observed departure from the highest calculated value. As percoades are always prevent in the electrolyte, it is concertable that such a counter E. M.F. may east, uncorever, there is also the possible influence of the lead support to be convoliered (5). That the observed loss of efficiency is to be attributed to

the formation of peroxides in the electrolyte, and to the excessive sulphating occurring chiefly at the peroxide plate in the local circuit existing between the support and the paste

June 18 — "Comparison of Simultaneous Magnetic Disturbances at several Observatories, and Determination of the Value of the Caussian Coefficients of Those Observatories". By 1rof, W. Grylle Adams, D.Sc., F.R.S., Profestor of Natural Philosophy in King's College, London.
After drawing attention to previous investigations on this

subject, and pointing out the importance of adopting the same scale values for similar instruments at different Observatories, especially at new Observatories which have I een recently established, the discussion of special magnetic disturbances is entaitished, the discossion of special magnetic disturbances is undertaken, especially the disturbances of a great magnetic storm which occurred on June 24 and 25, 1885, for which photographic records have been obtained from 17 different Oliservatories: 11 in Europe, 1 in Canada, 1 in India, 1 in China, 1 in Jan, 2 at Mantitus, and 1 at Mebourne.

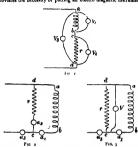

The records are discussed and compared, tables are formed of the amultaneous disturbances, and the traces are reduced to

Greenwich mean time and brought together on the same plates arranged on the same time-cale. Plates I, and II show the remarkable agreement between the disturbances at the different Observatories, and the tables show that the amount of dis-turbance, especially of horizontal magnetic force, is nearly the same at widely distant stations

An attea-pt has also been made to apply the Gaussian analysis to sudden magnetic disturbances, and, with a view to their application in future work, the values of the Gaussian coefficients have been obtained for 20 different Observatories, and the numerical equations formed for the elements of magnetic force in three directions mutually at right angles, and also the equation for the magnetic potential in terms of the Gaussian constants to the fourth order

The tables give the numerical values to be multiplied by the 24 Gaussian constants to give the values of the forces X, V, and Z in the geographical meridian towards the north, perpendicular to the meridian towards the west, and towards the earth's centre to the mendian towards the west, and towards the earth's centre respectively. The equations are also formed and the values obtained in terms of the 24 Gaussian constants for λ_p , λ_p and λ_q . λ_p being the horizontal force in the magnetic mendian, V_q , the horizontal force perpendicular to the magnetic mendian, and λ_q the vertical force. If then X_p , V_q , and Z_q be the observed values of any simultaneous disturbances, they may be at once substituted in the equations, the equations giving the 24 Gaussian constants may be solved, and the corresponding change of magnetic potential may be determined

Physical Society, June 12, 1891 -Prof W F Ayrton, F.R.S., President, in the chair.—Prof. W. F. Ayrton, F.R.S., President, in the chair.—Prof. W. G. Adams took the chair whilst Prof. Ayrton read a paper on alternate current and potential difference analogues in the methods of measuring power, by himstelf and Dr. Sumpmer. In a paper read before the Society in March last, the authon pointed out that, for every method of measuring power in which readings of that, for every method of measuring power in which readings of voits and suppers were taken, other methods in which ampieres of the method of the suppers of the supers of the supers of elevated. More recently, Dr. Flening had, by a transformation of a formula given by the authors an communication made to the Koyal Society on the measurement of power by three volt-the koyal Society on the measurement of power by three volt-heydown and the suppers of the supers of the suppers of the polyed. The two arrangements are represented in Figs. 1 and 2, whilst Fig. 3 shows a modification of Dr. Flening's method (Fig. 2, la which the current in the non-inductive resistance r is measured by the aid of a voltmeter V across its terminals. This obviates the necessity of putting an electro magnetic instrument

in what should be a non-inductive circuit. The formula for the mean watts spent in the circuit ab, Figs. 1 and 2, are respectively—

spectively—
$$W = \frac{1}{2r} \left(V_1^s - V_1^s - V_2^s \right), \text{ and } W = \frac{r}{2} \left(A_1^s - A_1^s - A_2^s \right).$$

Mr. Blackely's method of measuring power by a split-dynamonice was above to be analogous to the original electrometer method in which the difference of two readings was proportional to the power, and Blondiot and Currie's double electrometer method was shown to be the analogue of the ordinary swattmeter method was shown to be the analogue of the ordinary swattmeter The wattencier was effective in the fact that a subnordal cost was introduced is, as was shown by one of the authors some years ago, expressed by the formula—

Apparent watts =
$$\frac{1 + \tan \theta \cdot \tan \phi}{1 + \tan^2 \phi}$$

where 8 is the phase angle between the current and E M F the circuit in which the power is to oe measured, and o the phase angle for the approximately non-inductive circuit. now proved that the same formula expresses the error in any of the methods where resistances not wholly non inductive are used. the methods where resistances not wanty from inductive are used.

As is well known, Mr. Blakesley has applied his split-dynamo meter to the measurement of phase differences between two currents, and an analogous method of finding the phase difference between two potential differences is described in the paper. In this method a high resistance split-dynamometer such as suggested by Mr Rimington for measuring power is employed. Blondlot and Currie's double electrometer could also be used for the and Currie's double electrometer to the same purpose Numerous diagrams illustrating the various whether hot wire voltmeters could be employed to measure the various potential differences, without introducing error. In reply, Prof Ayrton said that, although no great error was introduced by the self-induction of these instruments, yet the fact that they required considerable current was a disadvantage, and as these currents were not always in the same phase as those in other circuits, troublesome corrections were sometimes necessary Electrostatic instruments were preferable Prof. Adams said he was glad to hear that the inductance of Cardew volumeters introduced no serious error, for they were very convenient instruments to use.—Prof. O. Lodge, F.R.S., exhibited and described a clock for pointing out the direction of the earth's orbital motion in the ether. After mentioning the various motions to which a point on the earth's surface is subjected, he pointed out that the orbital motion was the largest component, and its direction at any in-stant not easy to conceive. An apparatus for pointing out this direction was therefore convenient when dealing with problems

requiring a knowledge of the motion of a point through the ether. In one of two clocks shown, one spindle representing the earth's polar axis and another the axis of the coliptic were inearth's polar axis and another the axis of the ecliptic were in-clined at an angle of 33%; and coupled by a Hooke's joint. The latter axis was capable of rotating round the former. At its upper end the ecliptic axis carried a tube and a pointer, both being perpendicular to the axis and to each other. The clock keeping solar time rotated both axes, and when property set the tube pointed in the direction of the sun, and the pointer therefore in-dicated the direction of the earth's orbital motion —Some experiments with Leyden jars were then shown by Dr. Lodge. The first one was with resonant jars, in which the discharge of one jar precipitated the overflow of another, when the lengths of one jar presunsted the overlies a allosted or tuned. The latter jar was entirely disconnected from the former, and was influenced merely by electro-magnetic waves emanating from the discharging circuit. Lengthening or shortening either circuit prevented the circuit. Lengthening or snortening either circuit preventes the overflow. Correct tuning was, he said, of great importance in these experiments, for a dozen or more oscillations occurred before the discharge ceased. The effect could be shown over considerable distances in connection with this subject Mr. Blake-ley had called his attention to an observation made by Priestley many years ago, who noticed that, when several jara were being charged from the same prime conductor, if one of them discharged the others would sometimes also discharge, although they were not fully charged. This he (Dr. Lodge) thought might be due to the same kind of influence which he had just might be due to the same kind of influence which ne nau just shown to exist. The word retenance, he said, was often minderstood hy supposing it always had reference to sound, and as substitute he thought that symphomic or symphomic might be allowable. The next experiment was to show that wires might be tuned to respond to the oscillation of a jar discharge just as a string could be tuned to respond to a tuning-fork thin stietched wire was connected to the knob of a jar and ann arrefered wire was connected to the knob of a jur and another parallel one to its outer coating, and by varying the length of an independent discharging circuit, a glow was caused to appear along the remote halves of the stretched wirea at each discharge. Lach of the wires thus setted like a atopped organpipe, the remote ends being the nodes at which the variations no pressure were greatest. By using long wires he had observed a glow on portions of them with the internediate parts dark, this corresponded with the first harmonic, and by measuring the distance between two nodes he had determined the wave-length of the oscillation. The length so found did not agree very closely with the calculated length, and the discrepancy he thought due to the specific inductive capacity of the glass not being the same for such rapidly alternating pressures as for steady ones. He also showed that the electric pulses passing along a wire could be caused (by tuning) to react on the jar to which it was connected, and cause it to overflow even when the which it was connected, and cause it to overflow even when ine distance from the outside to the inside costing was about 8 inches. During this experiment he pointed out that the noise of the quark was greatly reduced by increasing the length of the discharging circuit. The same fact was also illustrated by causing two jars to discharge into each other, spark gaps being put both between their inner and outer coatings so as to obtain between their inner and outer coatings so as to obtain "A" sparks and "B" sparks by putting on a long "sliernative path" as a shunt to the B spark gap and increving that gap, the noise of the A spark was greatly reduced. He had reason to believe that the B spark was a quarter phase behind the A spark, that the experimental proof had not been completed. He next described some experiments on the screening of electro-magnetic radiation, in which a Hertz resonator was surrounded by different admitton, in which a Hetti re-onator was surrounded by different auternals. He had found no trace of opacity in missione, but missioned to the surrounded of the surrounded of the con-reconator. Cardboard rubbed with plumbage also acted like a nearly perfect screen. In connection with resonator, he ex-lubited what he called a graduated dictive or or an advire hard-er of the surrounded of the surrounded of the surrounded of of different length are attached to glass plate, and have spark gaps at each end which separate them from other pieces of foll. One or other of the strips would respond according to to the frequency of the electro-magnetic radiation falling upon it. Mr. Blakesley asked whether the pitch of the resonant pars altered when the distance between their circuits was warred, for according to theory the mutual induction should duminsh the self-induction, and cause the oscillations to be more rapid. If this occurred, the method might be used for getting rapid oscillations. He also inquired whether the glow would appear in the same position on the two stretched wires if their

salt were somed. Dr. Sampeer withelt to know how the seatance, indicatence, and chaptent of the circuits and juried statence, indicatence, and chapten of the live of the statence of introduces, and chapten of the live of the statence of irregular distribution of the charges on the title of land been noted. With reference to the overflowing of a jur caused by using a certain only prove the attainer of a higher potential than that which originally existed between the coatings of the jury, and, if so, where did the excess energy come from? Dr. Thompson asked originally existed between the coatings of the jury, and, if so, where did the excess energy come from? Dr. Thompson asked originally existed between the coatings of the jury, and, if so, where did the excess energy come from? Dr. Thompson asked originally existed between the coatings of the jury chapten of the company of the property of the state of the property of the propert
